# Background for Unification

---

- **Terms** made from **constructors** and **variables** (for the simple first order case)
- Constructors may be applied to arguments (other terms) to make new terms
- Variables and constructors with no arguments are base cases
- Constructors applied to different number of arguments (arity) considered different
- **Substitution** of terms for variables

# Simple Implementation Background

---

```
type term = Variable of string
          | Const of (string * term list)
```

```
let rec subst var_name residue term =
  match term with Variable name ->
    if var_name = name then residue else term
  | Const (c, tys) ->
    Const (c, List.map (subst var_name residue)
                    tys);;
```

# Unification Problem

---

Given a set of pairs of terms (“equations”)

$$\{(s_1, t_1), (s_2, t_2), \dots, (s_n, t_n)\}$$

(the *unification problem*) does there exist

a substitution  $\sigma$  (the *unification solution*)

of terms for variables such that

$$\sigma(s_i) = \sigma(t_i),$$

for all  $i = 1, \dots, n$ ?

# Uses for Unification

---

- Type Inference and type checking
- Pattern matching as in OCAML
  - Can use a simplified version of algorithm
- Logic Programming - Prolog
- Simple parsing

# Unification Algorithm

---

- Let  $S = \{(s_1, t_1), (s_2, t_2), \dots, (s_n, t_n)\}$  be a unification problem.
- Case  $S = \{ \}$ :  $\text{Unif}(S) = \text{Identity function}$  (i.e., no substitution)
- Case  $S = \{(s, t)\} \cup S'$  : Four main steps

# Unification Algorithm

---

- **Delete:** if  $s = t$  (they are the same term) then  $\text{Unif}(S) = \text{Unif}(S')$
- **Decompose:** if  $s = f(q_1, \dots, q_m)$  and  $t = f(r_1, \dots, r_m)$  (same  $f$ , same  $m!$ ), then  $\text{Unif}(S) = \text{Unif}(\{(q_1, r_1), \dots, (q_m, r_m)\} \cup S')$
- **Orient:** if  $t = x$  is a variable, and  $s$  is not a variable,  $\text{Unif}(S) = \text{Unif}(\{(x, s)\} \cup S')$

# Unification Algorithm

---

- **Eliminate:** if  $s = x$  is a variable, and  $x$  does not occur in  $t$  (the occurs check), then
  - Let  $\varphi = x \mapsto t$
  - Let  $\psi = \text{Unif}(\varphi(S'))$
  - $\text{Unif}(S) = \{x \mapsto \psi(t)\} \circ \psi$ 
    - Note:  $\{x \mapsto a\} \circ \{y \mapsto b\} = \{y \mapsto (\{x \mapsto a\}(b))\} \circ \{x \mapsto a\}$  if  $y$  not in  $a$

# Tricks for Efficient Unification

---

- Don't return substitution, rather do it incrementally
- Make substitution be constant time
  - Requires implementation of terms to use mutable structures (or possibly lazy structures)
  - We won't discuss these

# Example

---

- $x, y, z$  variables,  $f, g$  constructors
  
- $S = \{(f(x), f(g(y, z))), (g(y, f(y)), x)\}$

# Example

---

- $x, y, z$  variables,  $f, g$  constructors
- $S$  is nonempty
  
- $S = \{(f(x), f(g(y, z))), (g(y, f(y)), x)\}$

# Example

---

- $x, y, z$  variables,  $f, g$  constructors
- Pick a pair:  $(g(y, f(y)), x)$

$$\underbrace{f(g(y,f(y)))}_x = f(\underbrace{g(y,f(y))}_z)$$

and

$$g(y,f(y)) = \underbrace{g(y,f(y))}_x$$

- No rule to apply! Decompose fails!

# Example of Failure: Occurs Check
