## More Dynamic Programming

CS 473: Fundamental Algorithms, Spring 2013

February 16, 2013

### 9.1 Maximum Weighted Independent Set in Trees

#### 9.1.0.1 Maximum Weight Independent Set Problem

**Input** Graph  $G = (V, E)$  and weights  $w(v) \geq 0$  for each  $v \in V$

**Goal** Find maximum weight independent set in  $G$

Maximum weight independent set in above graph:  $\{B, D\}$

#### 9.1.0.2 Maximum Weight Independent Set in a Tree

**Input** Tree  $T = (V, E)$  and weights  $w(v) \geq 0$  for each  $v \in V$

**Goal** Find maximum weight independent set in  $T$

Maximum weight independent set in above tree: ??

#### 9.1.0.3 Towards a Recursive Solution

For an arbitrary graph  $G$ :

- (A) Number vertices as  $v_1, v_2, \dots, v_n$
- (B) Find recursively optimum solutions without  $v_n$  (recurse on  $G - v_n$ ) and with  $v_n$  (recurse on  $G - v_n - N(v_n)$  & include  $v_n$ ).

(C) Saw that if graph  $G$  is arbitrary there was no good ordering that resulted in a small number of subproblems.

What about a tree? Natural candidate for  $v_n$  is root  $r$  of  $T$ ?

#### 9.1.0.4 Towards a Recursive Solution

Natural candidate for  $v_n$  is root  $r$  of  $T$ ? Let  $\mathcal{O}$  be an optimum solution to the whole problem.

**Case**  $r \notin \mathcal{O}$  : Then  $\mathcal{O}$  contains an optimum solution for each subtree of  $T$  hanging at a child of  $r$ .

**Case**  $r \in \mathcal{O}$  : None of the children of  $r$  can be in  $\mathcal{O}$ .  $\mathcal{O} - \{r\}$  contains an optimum solution for each subtree of  $T$  hanging at a grandchild of  $r$ .

Subproblems? Subtrees of  $T$  hanging at nodes in  $T$ .

#### 9.1.0.5 A Recursive Solution

$T(u)$ : subtree of  $T$  hanging at node  $u$

$OPT(u)$ : max weighted independent set value in  $T(u)$

$$OPT(u) = \max \left\{ \sum_{v \text{ child of } u} OPT(v), w(u) + \sum_{v \text{ grandchild of } u} OPT(v) \right\}$$

#### 9.1.0.6 Iterative Algorithm

- (A) Compute  $OPT(u)$  bottom up. To evaluate  $OPT(u)$  need to have computed values of all children and grandchildren of  $u$
- (B) What is an ordering of nodes of a tree  $T$  to achieve above? Post-order traversal of a tree.

### 9.1.0.7 Iterative Algorithm

**MIS-Tree**( $T$ ):

Let  $v_1, v_2, \dots, v_n$  be a post-order traversal of nodes of  $T$

**for**  $i = 1$  **to**  $n$  **do**

$$M[v_i] = \max \left( \sum_{v_j \text{ child of } v_i} M[v_j], w(v_i) + \sum_{v_j \text{ grandchild of } v_i} M[v_j] \right)$$

**return**  $M[v_n]$  (\* Note:  $v_n$  is the root of  $T$  \*)

**Space:**  $O(n)$  to store the value at each node of  $T$

**Running time:**

- (A) Naive bound:  $O(n^2)$  since each  $M[v_i]$  evaluation may take  $O(n)$  time and there are  $n$  evaluations.
- (B) Better bound:  $O(n)$ . A value  $M[v_j]$  is accessed only by its parent and grand parent.

### 9.1.0.8 Example

### 9.1.0.9 Dominating set

**Definition 9.1.1.**  $G = (V, E)$ . The set  $X \subseteq V$  is a **dominating set**, if any vertex  $v \in V$  is either in  $X$  or is adjacent to a vertex in  $X$ .

**Problem 9.1.2.** Given weights on vertices, compute the **minimum** weight dominating set in  $G$ .

**Dominating Set** is **NP-Hard**!

## 9.2 DAGs and Dynamic Programming

### 9.2.0.10 Recursion and DAGs

**Observation 9.2.1.** *Let  $A$  be a recursive algorithm for problem  $\Pi$ . For each instance  $I$  of  $\Pi$  there is an associated **DAG**  $G(I)$ .*

- (A) Create directed graph  $G(I)$  as follows...
- (B) For each sub-problem in the execution of  $A$  on  $I$  create a node.
- (C) If sub-problem  $v$  depends on or recursively calls sub-problem  $u$  add directed edge  $(u, v)$  to graph.
- (D)  $G(I)$  is a **DAG**. Why? If  $G(I)$  has a cycle then  $A$  will not terminate on  $I$ .

### 9.2.1 Iterative Algorithm for...

#### 9.2.1.1 Dynamic Programming and DAGs

**Observation 9.2.2.** *An iterative algorithm  $B$  obtained from a recursive algorithm  $A$  for a problem  $\Pi$  does the following:*

*For each instance  $I$  of  $\Pi$ , it computes a topological sort of  $G(I)$  and evaluates sub-problems according to the topological ordering.*

- (A) Sometimes the **DAG**  $G(I)$  can be obtained directly without thinking about the recursive algorithm  $A$
- (B) In some cases (**not all**) the computation of an optimal solution reduces to a shortest/longest path in **DAG**  $G(I)$
- (C) Topological sort based shortest/longest path computation is dynamic programming!

### 9.2.2 A quick reminder...

#### 9.2.2.1 A Recursive Algorithm for weighted interval scheduling

Let  $O_i$  be value of an optimal schedule for the first  $i$  jobs.

```
Schedule( $n$ ):  
  if  $n = 0$  then return 0  
  if  $n = 1$  then return  $w(v_1)$   
   $O_{p(n)} \leftarrow$  Schedule( $p(n)$ )  
   $O_{n-1} \leftarrow$  Schedule( $n - 1$ )  
  if ( $O_{p(n)} + w(v_n) < O_{n-1}$ ) then  
     $O_n = O_{n-1}$   
  else  
     $O_n = O_{p(n)} + w(v_n)$   
  return  $O_n$ 
```

## 9.2.3 Weighted Interval Scheduling via...

### 9.2.3.1 Longest Path in a DAG

Given intervals, create a **DAG** as follows:

- (A) Create one node for each interval, plus a dummy sink node 0 for interval 0, plus a dummy source node  $s$ .
- (B) For each interval  $i$  add edge  $(i, p(i))$  of the length/weight of  $v_i$ .
- (C) Add an edge from  $s$  to  $n$  of length 0.
- (D) For each interval  $i$  add edge  $(i, i - 1)$  of length 0.

### 9.2.3.2 Example

### 9.2.3.3 Relating Optimum Solution

Given interval problem instance  $I$  let  $G(I)$  denote the **DAG** constructed as described.

**Claim 9.2.3.** *Optimum solution to weighted interval scheduling instance  $I$  is given by longest path from  $s$  to 0 in  $G(I)$ .*

Assuming claim is true,

- (A) If  $I$  has  $n$  intervals, **DAG**  $G(I)$  has  $n + 2$  nodes and  $O(n)$  edges. Creating  $G(I)$  takes  $O(n \log n)$  time: to find  $p(i)$  for each  $i$ . How?
- (B) Longest path can be computed in  $O(n)$  time — recall  $O(m + n)$  algorithm for shortest/longest paths in **DAGs**.

### 9.2.3.4 DAG for Longest Increasing Sequence

Given sequence  $a_1, a_2, \dots, a_n$  create **DAG** as follows:

- (A) add sentinel  $a_0$  to sequence where  $a_0$  is less than smallest element in sequence
- (B) for each  $i$  there is a node  $v_i$
- (C) if  $i < j$  and  $a_i < a_j$  add an edge  $(v_i, v_j)$
- (D) find longest path from  $v_0$

## 9.3 Edit Distance and Sequence Alignment

### 9.3.0.5 Spell Checking Problem

Given a string “exponen” that is not in the dictionary, how should a spell checker suggest a *nearby* string?

What does nearness mean?

**Question:** Given two strings  $x_1x_2 \dots x_n$  and  $y_1y_2 \dots y_m$  what is a *distance* between them?

**Edit Distance:** minimum number of “edits” to transform  $x$  into  $y$ .

### 9.3.0.6 Edit Distance

**Definition 9.3.1.** *Edit distance* between two words  $X$  and  $Y$  is the number of letter insertions, letter deletions and letter substitutions required to obtain  $Y$  from  $X$ .

**Example 9.3.2.** The edit distance between *FOOD* and *MONEY* is at most 4:

FOOD  $\rightarrow$  MOOD  $\rightarrow$  MONOD  $\rightarrow$  MONED  $\rightarrow$  MONEY

### 9.3.0.7 Edit Distance: Alternate View

**Alignment** Place words one on top of the other, with gaps in the first word indicating insertions, and gaps in the second word indicating deletions.

F	O	O	D	
M	O	N	E	Y

### 9.3.0.8 Edit Distance Problem

### 9.3.0.9 Applications

- ### 9.3.0.10 Similarity Metric

*Edit distance is special case when  $\delta = \alpha_{pq} = 1$ .*

### Example 9.3.4.

*Alternative:*

Or a really stupid solution (delete string, insert other string):

$$Cost = 19\delta.$$

**Goal** Find alignment of minimum cost

### 9.3.1 Edit distance

#### 9.3.1.1 Basic observation

Let  $X = \alpha x$  and  $Y = \beta y$

$\alpha, \beta$ : strings.

$x$  and  $y$  single characters.

Think about optimal edit distance between  $X$  and  $Y$  as alignment, and consider last column of alignment of the two strings:

$\alpha$	$x$	or	$\alpha$	$x$	or	$\alpha x$	
$\beta$	$y$		$\beta y$			$\beta$	$y$

**Observation 9.3.5.** *Prefixes must have optimal alignment!*

#### 9.3.1.2 Problem Structure

**Observation 9.3.6.** *Let  $X = x_1 x_2 \cdots x_m$  and  $Y = y_1 y_2 \cdots y_n$ . If  $(m, n)$  are not matched then either the  $m$ th position of  $X$  remains unmatched or the  $n$ th position of  $Y$  remains unmatched.*

(A) **Case**  $x_m$  and  $y_n$  are matched.

(A) Pay mismatch cost  $\alpha_{x_m y_n}$  plus cost of aligning strings  $x_1 \cdots x_{m-1}$  and  $y_1 \cdots y_{n-1}$

(B) **Case**  $x_m$  is unmatched.

(A) Pay gap penalty plus cost of aligning  $x_1 \cdots x_{m-1}$  and  $y_1 \cdots y_n$

(C) **Case**  $y_n$  is unmatched.

(A) Pay gap penalty plus cost of aligning  $x_1 \cdots x_m$  and  $y_1 \cdots y_{n-1}$

#### 9.3.1.3 Subproblems and Recurrence

Optimal Costs Let  $\text{Opt}(i, j)$  be optimal cost of aligning  $x_1 \cdots x_i$  and  $y_1 \cdots y_j$ . Then

$$\text{Opt}(i, j) = \min \begin{cases} \alpha_{x_i y_j} + \text{Opt}(i-1, j-1), \\ \delta + \text{Opt}(i-1, j), \\ \delta + \text{Opt}(i, j-1) \end{cases}$$

Base Cases:  $\text{Opt}(i, 0) = \delta \cdot i$  and  $\text{Opt}(0, j) = \delta \cdot j$

#### 9.3.1.4 Dynamic Programming Solution

```

for all  $i$  do  $M[i, 0] = i\delta$ 
for all  $j$  do  $M[0, j] = j\delta$ 

for  $i = 1$  to  $m$  do
  for  $j = 1$  to  $n$  do
     $M[i, j] = \min \begin{cases} \alpha_{x_i y_j} + M[i-1, j-1], \\ \delta + M[i-1, j], \\ \delta + M[i, j-1] \end{cases}$ 

```

Figure 9.1: Iterative algorithm in previous slide computes values in row order. Optimal value is a shortest path from  $(0,0)$  to  $(m,n)$  in DAG.

Analysis

- (A) Running time is  $O(mn)$ .
- (B) Space used is  $O(mn)$ .

#### 9.3.1.5 Matrix and DAG of Computation

#### 9.3.1.6 Sequence Alignment in Practice

- (A) Typically the DNA sequences that are aligned are about  $10^5$  letters long!
- (B) So about  $10^{10}$  operations and  $10^{10}$  bytes needed
- (C) The killer is the 10GB storage
- (D) Can we reduce space requirements?

#### 9.3.1.7 Optimizing Space

- (A) Recall

$$M(i, j) = \min \begin{cases} \alpha_{x_i y_j} + M(i-1, j-1), \\ \delta + M(i-1, j), \\ \delta + M(i, j-1) \end{cases}$$

- (B) Entries in  $j$ th column only depend on  $(j-1)$ st column and earlier entries in  $j$ th column
- (C) Only store the current column and the previous column reusing space;  $N(i, 0)$  stores  $M(i, j-1)$  and  $N(i, 1)$  stores  $M(i, j)$

Figure 9.2:  $M(i, j)$  only depends on previous column values. Keep only two columns and compute in column order.

### 9.3.1.8 Computing in column order to save space

#### 9.3.1.9 Space Efficient Algorithm

```

for all  $i$  do  $N[i, 0] = i\delta$ 
for  $j = 1$  to  $n$  do
   $N[0, j] = j\delta$  (* corresponds to  $M(0, j)$  *)
  for  $i = 1$  to  $m$  do
    
$$N[i, j] = \min \begin{cases} \alpha_{x_i y_j} + N[i-1, j] \\ \delta + N[i-1, j-1] \\ \delta + N[i, j-1] \end{cases}$$

  for  $i = 1$  to  $m$  do
    Copy  $N[i, 0] = N[i, j]$ 

```

Analysis Running time is  $O(mn)$  and space used is  $O(2m) = O(m)$

#### 9.3.1.10 Analyzing Space Efficiency

- (A) From the  $m \times n$  matrix  $M$  we can construct the actual alignment (exercise)
- (B) Matrix  $N$  computes cost of optimal alignment but no way to construct the actual alignment
- (C) Space efficient computation of alignment? More complicated algorithm — see text book.

#### 9.3.1.11 Takeaway Points

- (A) Dynamic programming is based on finding a recursive way to solve the problem. Need a recursion that generates a small number of subproblems.
- (B) Given a recursive algorithm there is a natural **DAG** associated with the subproblems that are generated for given instance; this is the dependency graph. An iterative algorithm simply evaluates the subproblems in some topological sort of this **DAG**.

- (C) The space required to evaluate the answer can be reduced in some cases by a careful examination of that dependency **DAG** of the subproblems and keeping only a subset of the **DAG** at any time.
