

Iterators

In C++, iterators provide an interface for client code access to data in a way that abstracts away the internals of the data structure.

An instance of an iterator is a current location in a pass through the data structure:

| Type | Cur. Location | Current Data | Next |
|-------------|---------------|--------------|------|
| Linked List | | | |
| Array | | | |
| Hypercube | | | |

The iterator minimally implements three member functions:

- `operator*`, Returns the current data
- `operator++`, Advance to the next data
- `operator!=`, Determines if the iterator is at a different location

Implementing an Iterator

A class that implements an iterator must have two pieces:

1. [Implementing Class]: Must implement:

-

-

2. [Implementing Class' Iterator]:

A separate class (usually an internal class) that extends `std::iterator` and implements an iterator. This requires:

-

-

-

Locations of `::begin()` and `::end()` iterators:

| Type | <code>::begin()</code> | <code>::end()</code> |
|-------------|------------------------|----------------------|
| Linked List | | |
| Array | | |

Using an Iterator

```

stlList.cpp
1  #include <vector>
2  #include <string>
3  #include <iostream>
4
5  struct Animal {
6      std::string name, food;
7      bool big;
8      Animal(std::string name = "blob", std::string food = "you",
9      bool big = true) :
10         name(name), food(food), big(big) { /* nothing */ }
11 };
12
13 int main() {
14     Animal g("giraffe", "leaves", true),
15         p("penguin", "fish", false), b("bear");
16     std::vector<Animal> zoo;
17
18     zoo.push_back(g);
19     zoo.push_back(p); // std::vector's insertAtEnd
20     zoo.push_back(b);
21
22     for ( std::vector<Animal>::iterator it = zoo.begin();
23           it != zoo.end(); it++ ) {
24         std::cout << (*it).name << " " << (*it).food << std::endl;
25     }
26
27     return 0;
28 }

```

Q: What does the above code do?

For-Each loop with Iterators

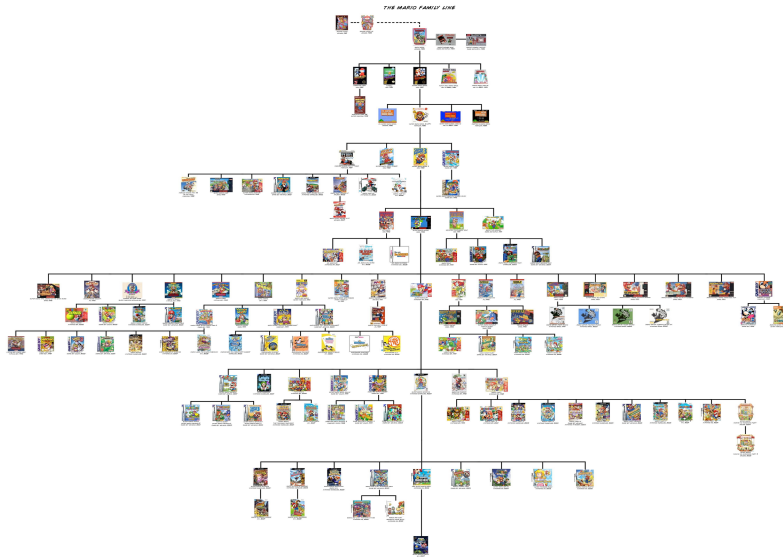

```

stlList-forEach.cpp
20 for ( const Animal & animal : zoo ) {
21     std::cout << animal.name << " " << animal.food << std::endl;
22 }

```

Trees!

“The most important non-linear data structure in computer science.”
 - David Knuth, *The Art of Programming, Vol. 1*

We will primarily talk about **binary trees**:

- What’s the longest **English word** you can make using the **vertex** labels in the tree (repeats allowed)?
- Find an **edge** that is not on the longest **path** in the tree. Give that edge a reasonable name.
- One of the vertices is called the **root** of the tree. Which one?
- Make a “word” containing the names of the vertices that have a **parent** but no **sibling**.
- How many parents does each vertex have?
- Which vertex has the fewest **children**?
- Which vertex has the most **ancestors**?
- Which vertex has the most **descendants**?
- List all the vertices in b’s left **subtree**.
- List all the **leaves** in the tree.

Definition: Binary Tree

A *binary tree* **T** is either:

Tree Property: Tree Height

Tree Property: Full

Tree Property: Perfect

Tree Property: Complete

CS 225 – Things To Be Doing:

1. Programming Exam A starts tomorrow (Thursday!)
2. MP3 has been released; extra credit deadline is Monday!
3. lab_quacks in lab this week
4. Daily POTDs
