

C No Evil

A practitioner's guide

[Playing with fire]

- Typcasting
- Program arguments
- Pointer arithmetic
- Output
- Stack memory

Typecasting

[Typecasting]

- C allows programmers to perform typecasting by
 - Place the type name in parentheses and place this in front of the value

```
main() {  
    float a;  
    a = (float)5 / 3;  
}
```

- Result is $a = 1.666666$
 - Integer 5 is converted to floating point value before division and the operation between float and integer results in float
- What would `a` be without the `(float)`?

[Typecasting]

- Take care about using typecast
- If used incorrectly, may result in loss of data
 - e.g., truncating a `float` when casting to an `int`

[Typecasting pointers]

```
int* p = 160;

printf("%p %p %p\n",
       p, p+1,
       ((char*) p) + 1
);
```

- Does not change pointer value
- Does affect pointer arithmetic

[Typecasting pointers]

```
int* p = 160;

printf("%p %p %p\n",
       p, p+1,
       ((char*) p) + 1
);
```

- It works, but compiler complains....
→ **warning**: incompatible integer to pointer conversion initializing 'int *' with an expression of type 'int'

[Typecasting pointers]

```
int* p = (int*) 160;

printf("%p %p %p\n",
       p, p+1,
       ((char*) p) + 1
);
```

- Does not change pointer value
- Does affect pointer arithmetic
- **Avoids compiler warnings**

[What type are we using?]

```
int x;
```

```
((char*) &x) [0] = 'f';  
((char*) &x) [1] = 'u';  
((char*) &x) [2] = 'n';  
((char*) &x) [3] = '\\0';
```

```
printf("This class is %s.\\n", &x);  
printf("Hexadecimal value of x is %x.\\n", x);
```

Are we dealing with strings
or numbers?

[What type are we using?]

```
int x;  
  
( (char*) &x) [0] = 'f';  
( (char*) &x) [1] = 'u';  
( (char*) &x) [2] = 'n';  
( (char*) &x) [3] = '\0';
```

Are we dealing with strings
or numbers?

They are just a sequence
of bytes “interpreted” as
different types

```
printf("This class is %s.\n", &x);  
printf("Hexadecimal value of x is %x.\n", x);
```

Output:

This class is fun.

The dec and hex value of x are 7239014

| \0 | n | u | f |

6e7566.

[What is endianness?]

```
int x;
```

```
((char*) &x) [0] = 'f';  
((char*) &x) [1] = 'u';  
((char*) &x) [2] = 'n';  
((char*) &x) [3] = '\\0';
```

```
printf("This class is %s.\n", &x);  
printf("Hexadecimal value of x is %x.\n", x);
```

Endianness: are integers represented with the most significant byte stored at the lowest address (big endian) or at the highest address (little endian)?

[What is endianness?]

```
int x;  
  
( (char*) &x) [0] = 'f';  
( (char*) &x) [1] = 'u';  
( (char*) &x) [2] = 'n';  
( (char*) &x) [3] = '\0';
```

Quiz: based on the output, can you tell what is the endianness of this machine?

```
printf("This class is %s.\n", &x);  
printf("Hexadecimal value of x is %x.\n", x);
```

Output:

This class is fun.

The dec and hex value of x are 7239014 6e7566.

| \0 | n | u | f |

[ARGCount ARGValues]

```
int main(argc, char** argv)
```

```
int main(argc, char* argv[])
```

■ argc

- Argument count
- The number of arguments that are passed to `main` in the argument vector `argv`.
- the value of `argc` is always one greater than the number of command-line arguments that the user enters.

[ARGCount ARGValues]

```
int main(argc, char** argv)
```

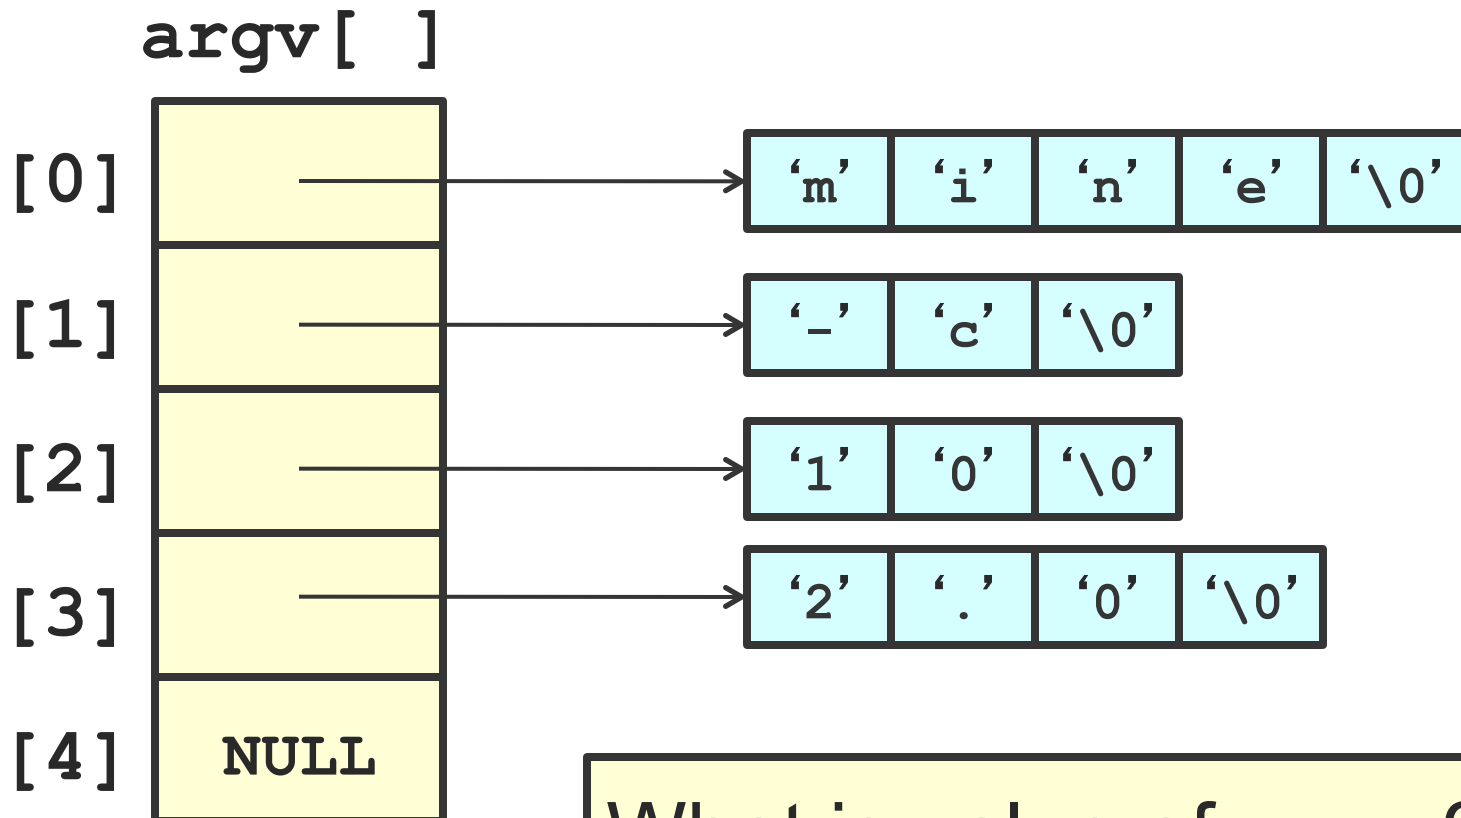

```
int main(argc, char* argv[])
```

- `argv`

- argument vector
- An array of string pointers passed to a C program's `main` function
- `argv[0]` is always the name of the command
- `argv[argc]` is a null pointer

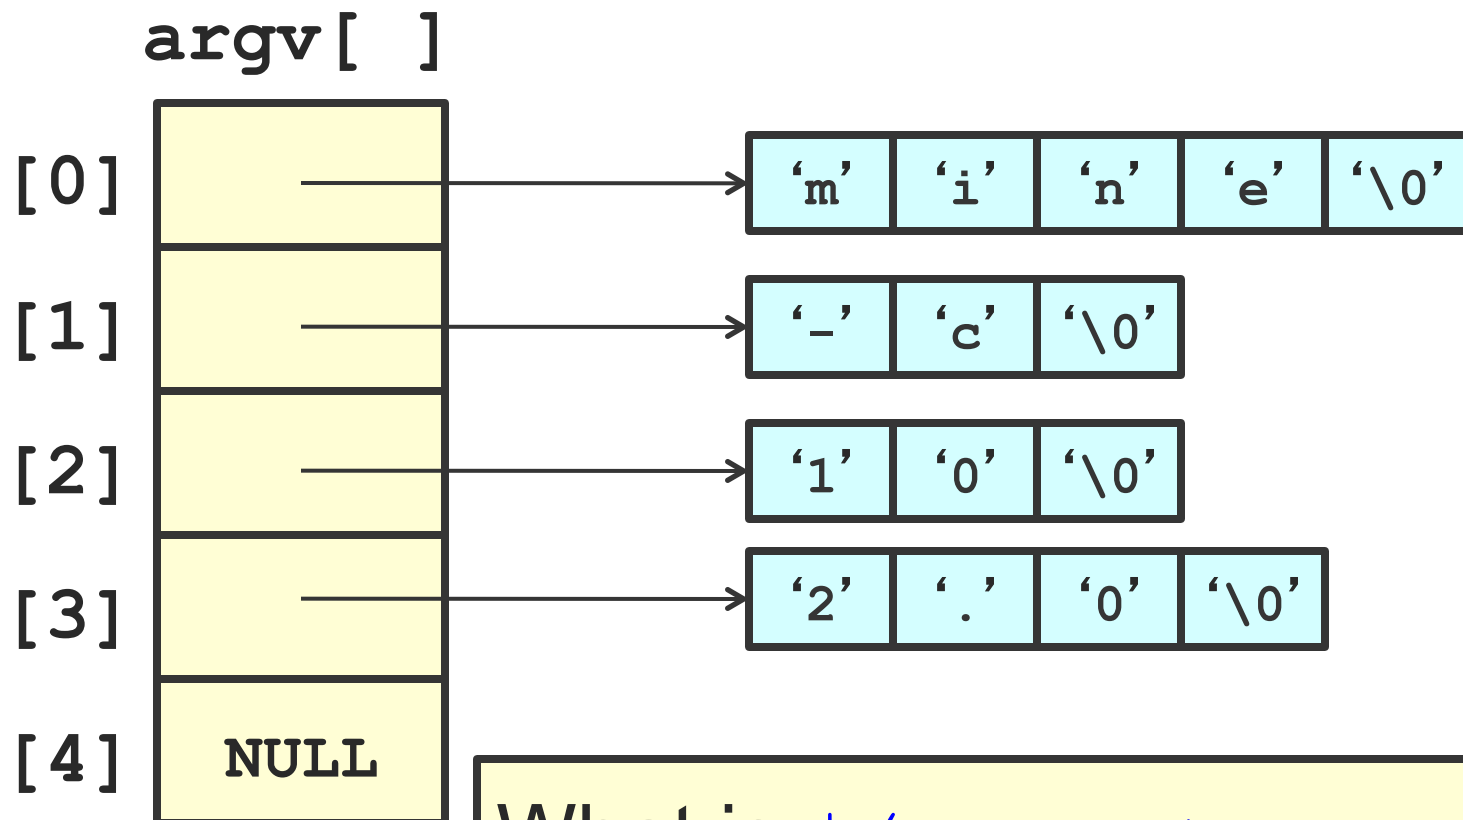

[ARGCount ARGValues]

What is value of `argc`?

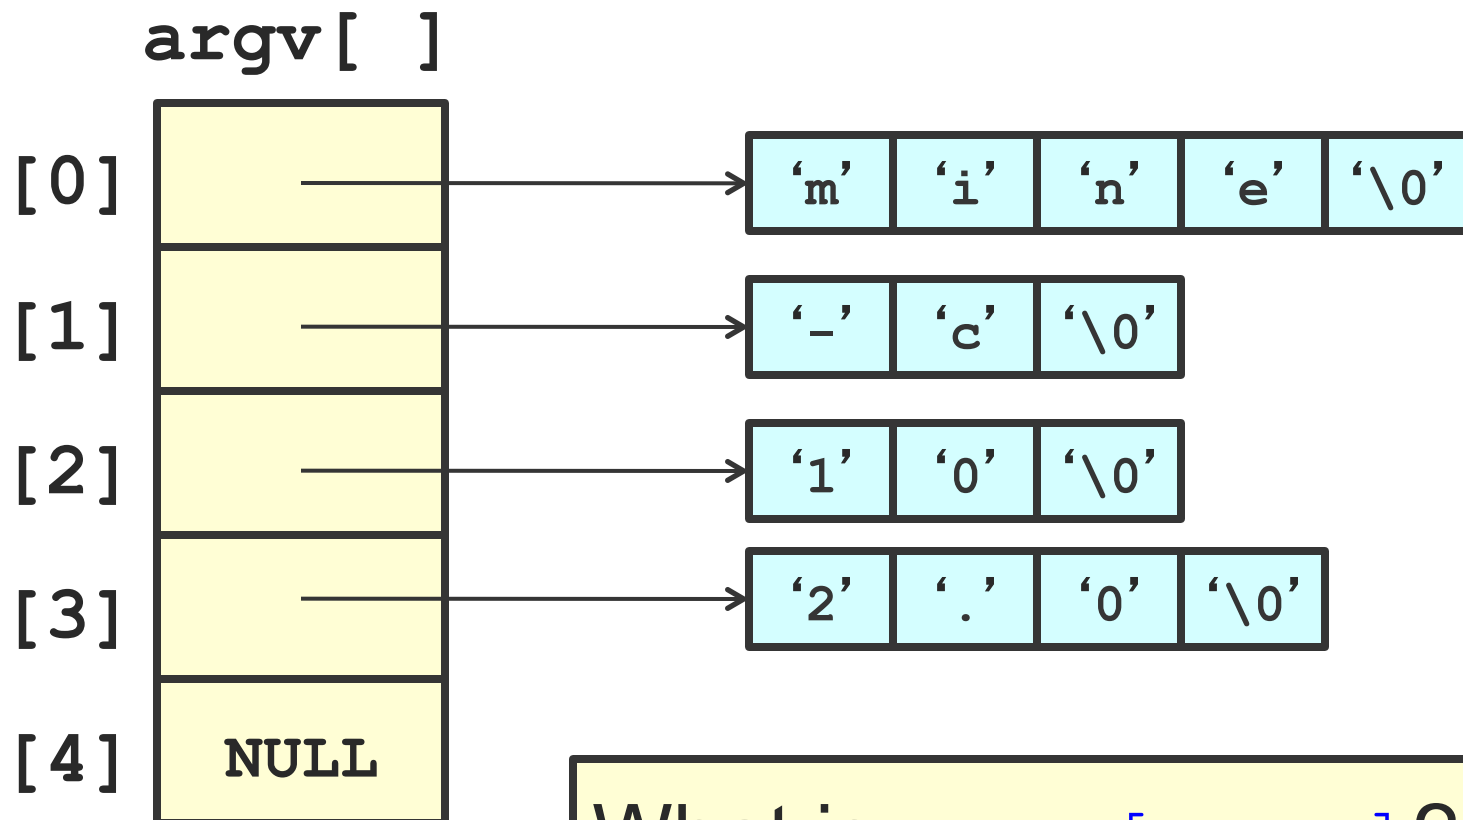

[ARGCount ARGValues]

What is $*(\text{argv} + \text{argc})$?

[ARGCount ARGValues]

What is `argv[argc]`?

[Type questions]

- `char **argv;`

What type is `argv`?

What type is `*argv`?

What type is `**argv`?

[Adding integers to pointers]

- Compiler uses the type information

- `long *p;`

- `p` ▶ `[long] [long] [long]`

- What address is `p + 2`?

- ... `p + sizeof(long) * 2`

[Output]

- C stdio library functions

```
printf("Hello %x %s %d", arguments...)  
fprintf(STDERR, "%x%s%d", ...)
```

[printf Format Identifiers]

<code>%d</code> or <code>%i</code>	Decimal signed integer
<code>%o</code>	Octal integer
<code>%x</code> or <code>%X</code>	Hex integer
<code>%u</code>	Unsigned integer
<code>%c</code>	Character
<code>%s</code>	String
<code>%f</code> or <code>%g</code>	Double
<code>%p</code>	Pointer

All of the parameters should be the value to be inserted
EXCEPT `%s`, this expects a pointer to be passed

[printf Basic Data Types]

```
#include <stdio.h> // for printf
int main(int argc, char *argv[]) {

    // - print 8-digit hex value
    // - print a pointer value
    unsigned long ulID = 0x12345678;
    unsigned long *pID = &ulID;
    printf("hex value: 0x%lX at address: %p\n", ulID, pID);

    // - print 4 bytes of a 32-bit ulong value
    // as separate hex values
    unsigned char uc1 = (unsigned char) (ulID >> 24);
    unsigned char uc2 = (unsigned char) (ulID >> 16);
    unsigned char uc3 = (unsigned char) (ulID >> 8);
    unsigned char uc4 = (unsigned char) (ulID >> 0);
    printf("hex bytes: %X %X %X %X\n", uc1, uc2, uc3, uc4);
}
```

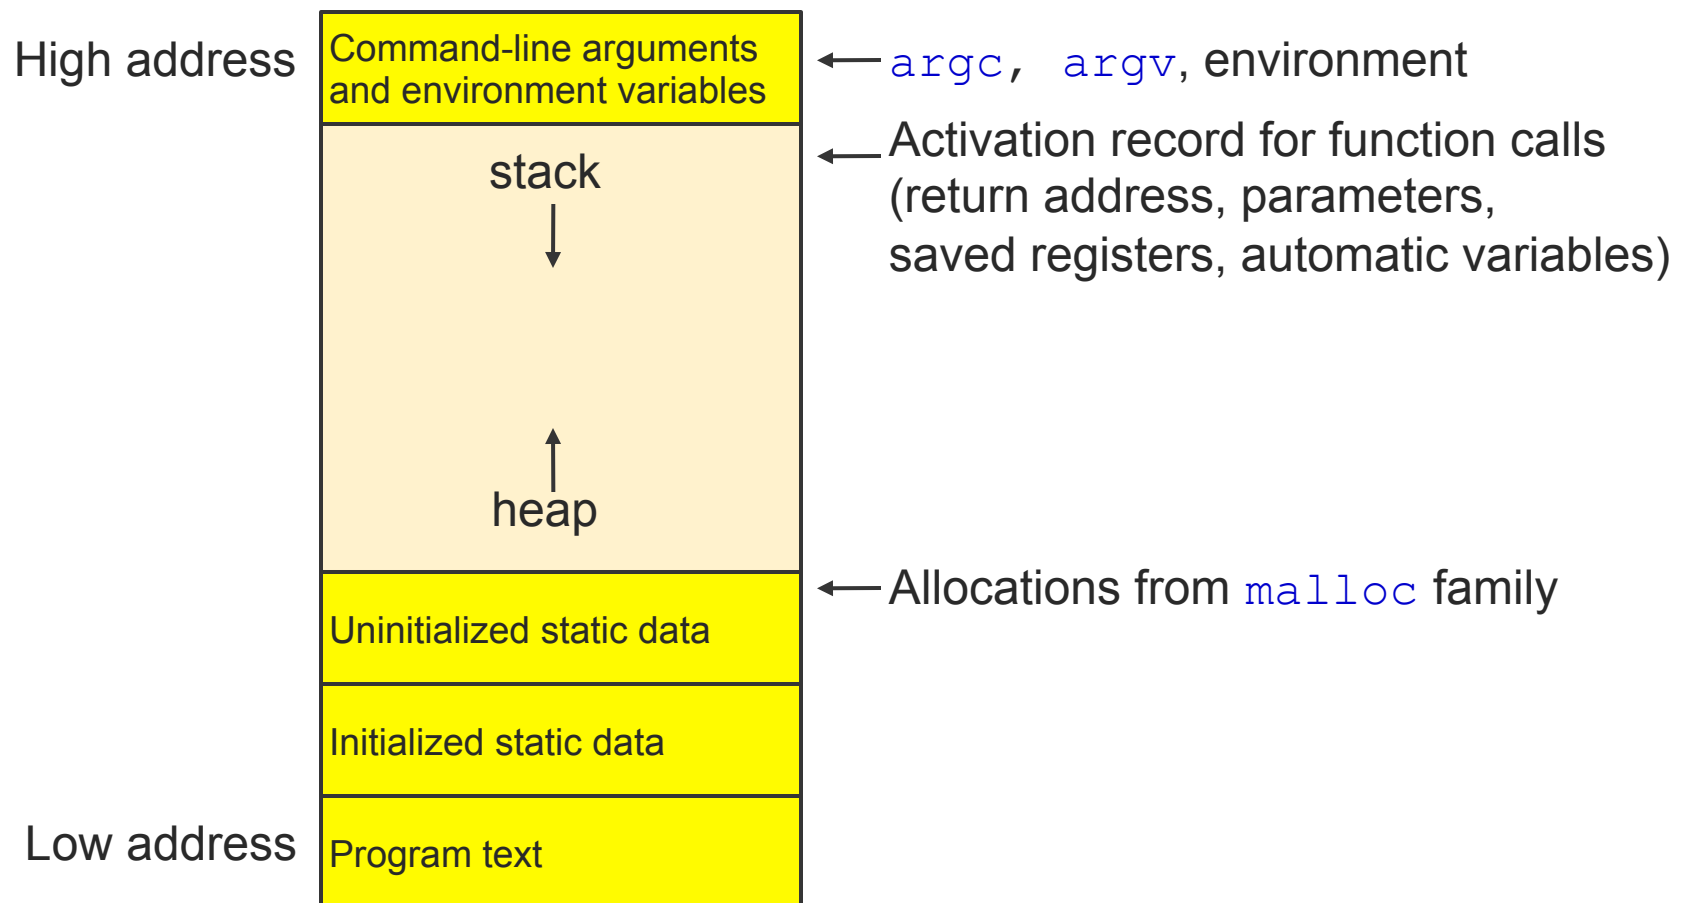

[Common Pitfall]

- Returning a variable in stack memory from a function
 - What is stack memory?

Sample layout for program image in main memory

[Example]

```
int b() {  
    /* ... */  
}
```

```
int a() {  
    /* ... */  
    b();  
}
```

```
int main(int argc,  
         char **argv) {  
    /* ... */  
    a();  
}
```

[Example]

```
int b() {  
    /* ... */  
}
```

```
int a() {  
    /* ... */  
    b();  
}
```

```
int main(int argc,  
char **argv) {  
    /* ... */  
    a();  
}
```

At the beginning of the program, the OS creates a stack frame for `main()`

Stack Memory:

[Example]

```
int b() {  
    /* ... */  
}
```

```
int a() {  
    /* ... */  
    b();  
}
```

```
int main(int argc,  
char **argv) {  
    /* ... */  
    a();  
}
```

When `a()` is called, the OS creates a new stack frame for `a()`

Stack Memory:

[Example]

→ `int b() {
 /* ... */
}`

→ `int a() {
 /* ... */
 b();
}`

→ `int main(int argc,
char **argv) {
 /* ... */
 a();
}`

Same for b () ...

Stack Memory:

[Example]

```
int b() {  
    /* ... */  
}
```

```
int a() {  
    /* ... */  
    b();  
}
```

```
int main(int argc,  
char **argv) {  
    /* ... */  
    a();  
}
```

When `b()` finishes running, its stack frame is removed!

What happens to the memory?

Stack Memory:

[Example]

```
int b() {  
    /* ... */  
}
```

```
int a() {  
    /* ... */  
    b();  
}
```

```
int main(int argc,  
char **argv) {  
    /* ... */  
    a();  
}
```

When `b()` finishes running, its stack frame is removed!

What happens to the memory?

Stack Memory:

[Example]

And so on ...

```
int b() {  
    /* ... */  
}
```

```
int a() {  
    /* ... */  
    b();  
}
```

```
int main(int argc,  
char **argv) {  
    /* ... */  
    a();  
}
```

Stack Memory:

[Example]

And so on ...

```
int b() {  
    /* ... */  
}
```

```
int a() {  
    /* ... */  
    b();  
}
```

```
int main(int argc,  
char **argv) {  
    /* ... */  
    a();  
}
```

So What?

Stack Memory:

[Better Example]

```
my_queue * b() {  
    my_queue q;  
    return &q;  
}
```

```
int a(int yourVal) {  
    int myVal;  
    my_queue *myQueue;  
    myVal = yourVal + 3;  
    myQueue = b();  
    return  
        remove_int(myQueue);  
}
```

```
int main(int argc,  
         char **argv) {  
    int myVal = 3;  
    a(myVal);  
}
```

[Better Example]

```
my_queue * b() {  
    my_queue q;  
    return &q;  
}
```

```
int a(int yourVal) {  
    int myVal;  
    my_queue *myQueue;  
    myVal = yourVal + 3;  
    myQueue = b();  
    return  
        remove_int(myQueue);  
}
```

```
int main(int argc,  
         char **argv) {  
    int myVal = 3;  
    a(myVal);  
}
```

main() still calls a()
a() still calls b()
b() returns a pointer to a()
a() returns an int to main()
my_queue is a custom struct

[Better Example]

```
my_queue * b() {  
    my_queue q;  
    return &q;  
}
```

```
int main(int argc,  
        char **argv) {  
    int myVal = 3;  
    a(myVal);  
}
```

```
int a(int yourVal) {  
    int myVal;  
    my_queue *myQueue;  
    myVal = yourVal + 3;  
    myQueue = b();  
    return  
        remove_int(myQueue);  
}
```

[Better Example]

```
my_queue * b() {  
    my_queue q;  
    return &q;  
}
```

```
int main(int argc,  
         char **argv) {  
    int myVal = 3;  
    a(myVal);  
}
```

```
int a(int yourVal) {  
    int myVal;  
    my_queue *myQueue;  
    myVal = yourVal + 3;  
    myQueue = b();  
    return  
        remove_int(myQueue);  
}
```

myVal (4 bytes)	3
**argv (8 bytes)	0x...
argc (4 bytes)	1

[Better Example]

```
my_queue * b() {  
    my_queue q;  
    return &q;  
}
```

```
int main(int argc,  
char **argv) {  
    int myVal = 3;  
    a(myVal);  
}
```

```
int a(int yourVal) {  
    int myVal;  
    my_queue *myQueue;  
    myVal = yourVal + 3;  
    myQueue = b();  
    return  
        remove_int(myQueue);  
}
```

yourVal (4 bytes)	3
myVal (4 bytes)	3
**argv (8 bytes)	0x...
argc (4 bytes)	1

[Better Example]

```
my_queue * b() {  
    my_queue q;  
    return &q;  
}
```

```
int main(int argc,  
char **argv) {  
    int myVal = 3;  
    a(myVal);  
}
```

```
int a(int yourVal) {  
    int myVal;  
    my_queue *myQueue;  
    myVal = yourVal + 3;  
    myQueue = b();  
    return  
        remove_int(myQueue);  
}
```

myVal (4 bytes)	???????
yourVal (4 bytes)	3
myVal (4 bytes)	3
**argv (8 bytes)	0x...
argc (4 bytes)	1

[Better Example]

```
my_queue * b() {
    my_queue q;
    return &q;
}
```

```
int main(int argc,
char **argv) {
    int myVal = 3;
    a(myVal);
}
```

```
int a(int yourVal) {
    int myVal;
    my_queue *myQueue;
    myVal = yourVal + 3;
    myQueue = b();
    return
        remove_int(myQueue);
}
```

[Better Example]

```
my_queue * b() {  
    my_queue q;  
    return &q;  
}
```

```
int main(int argc,  
char **argv) {  
    int myVal = 3;  
    a(myVal);  
}
```

```
int a(int yourVal) {  
    int myVal;  
    my_queue *myQueue;  
    myVal = yourVal + 3;  
    myQueue = b();  
    return  
        remove_int(myQueue);  
}
```

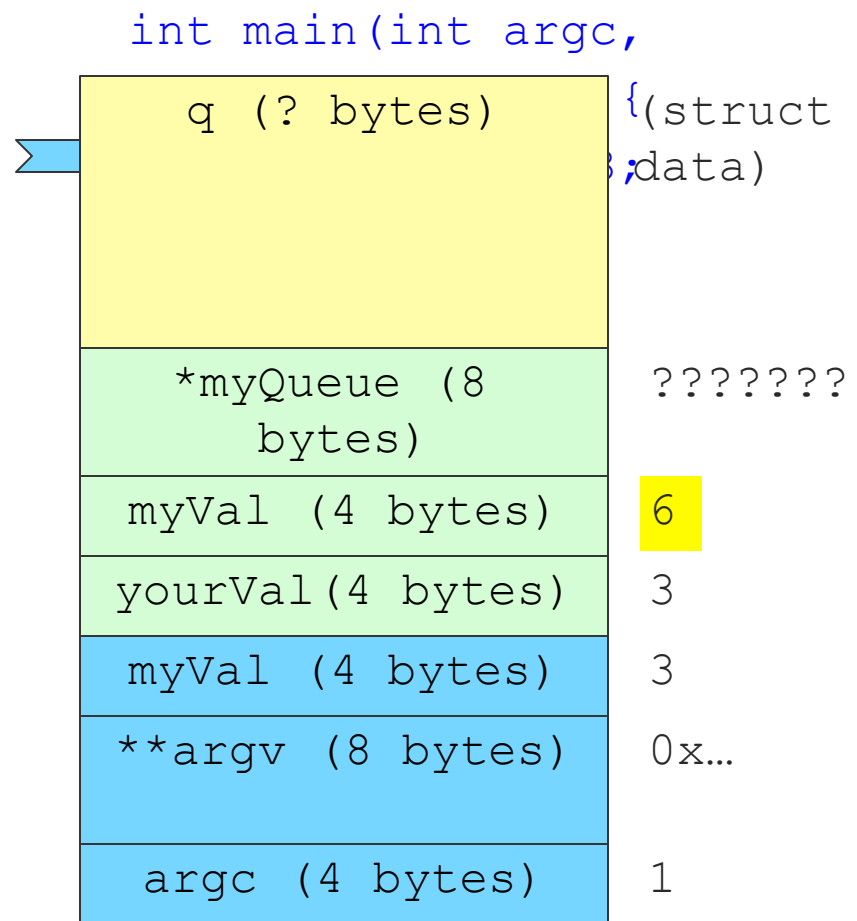

*myQueue (8 bytes)	???????
myVal (4 bytes)	6
yourVal (4 bytes)	3
myVal (4 bytes)	3
**argv (8 bytes)	0x...
argc (4 bytes)	1

[Better Example]

```
my_queue * b() {  
    my_queue q;  
    return &q;  
}  
  
int a(int yourVal) {  
    int myVal;  
    my_queue *myQueue;  
    myVal = yourVal + 3;  
    myQueue = b();  
    return  
        remove_int(myQueue);  
}
```

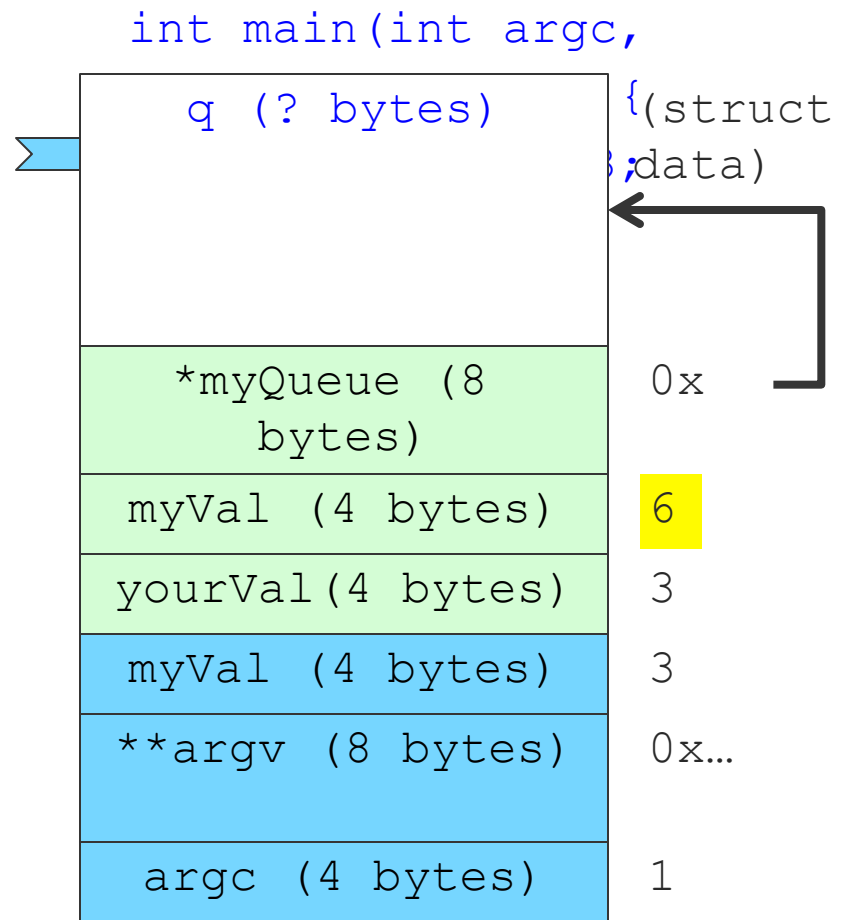

[Better Example]

```

my_queue * b() {
    my_queue q;
    → return &q;
}

int a(int yourVal) {
    int myVal;
    my_queue *myQueue;
    myVal = yourVal + 3;
    → myQueue = b();
    return
        remove_int(myQueue);
}

```

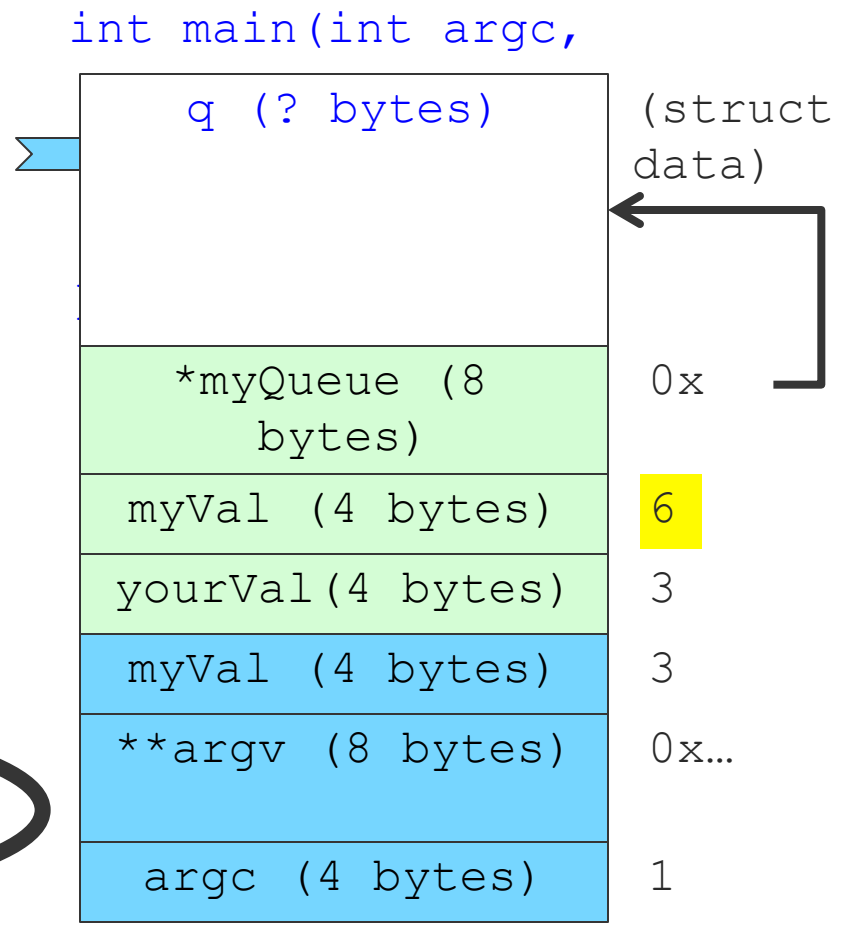

[Better Example]

```

my_queue * b() {
    my_queue q;
    return &q;
}

int a(int yourVal) {
    int myVal;
    my_queue *myQueue;
    myVal = yourVal + 3;
    myQueue = b();
    return
    remove_int(myQueue);
}

```

[Use your stack wisely]

- Returning a pointer to a stack variable results in unpredictable behavior
- Three ‘common’ fixes
 - Good: Pass in a pointer to the variable you want to use
 - Good: Use a heap variable
 - Bad (usually): Use a global variable
