

Errors

Scientific Notation

In **scientific notation**, a number can be expressed in the form

$$x = \pm r \times 10^m$$

where r is a coefficient in the range $1 \leq r < 10$ and m is the exponent.

Binary numbers

- We will soon be learning about how numbers are represented in the computer.
- Before we introduce this new concept, make sure to revise binary number representation. You will need to know how to convert from binary numbers to decimal numbers and vice-versa.
- To help you with the review, I added a PrairieLearn homework assignment, where you can get extra credit points (counting towards the “short questions”).

Error in Numerical Methods

- Every result we compute in Numerical Methods contain errors!
- We always have them... so our job? Reduce the impact of the errors
- How can we model the error?

- Absolute errors can be misleading, depending on the magnitude of the true value x .
- Example:
- Relative error is independent of magnitude!

You are tasked with measuring the height of a tree which is known to be exactly 170 ft tall. You later realized that your measurement tools are somewhat faulty, up to a relative error of 10%. What is the maximum measurement for the tree height (numbers rounded to 3 sig figs)?

- A) 153 ft
- B) 155 ft
- C) 187 ft
- D) 189 ft

You are tasked with measuring the height of a tree and you get the measurement as 170 ft tall. You later realized that your measurement tools are somewhat faulty, up to a relative error of 10%. What is the minimum height of the tree (numbers rounded to 3 sig figs) ?

- A) 153 ft
- B) 155 ft
- C) 187 ft
- D) 189 ft

Significant digits

Significant figures of a number are digits that carry meaningful information. They are digits beginning to the leftmost nonzero digit and ending with the rightmost “correct” digit, including final zeros that are exact.

The number 3.14159 has _____ significant digits.

The number 0.00035 has _____ significant digits.

The number 0.000350 has _____ significant digits.

Suppose x is the true value and \tilde{x} the approximation.

The number of significant figures tells us about how many positions of x and \hat{x} agree.

Suppose the true value is

$$x = 3.141592653$$

And the approximation is

$$\hat{x} = 3.14$$

We say that \hat{x} has _____ significant figures of x

Let's try the same for:

2) $\hat{x} = 3.14159$

3) $\hat{x} = 3.1415$

\hat{x} has **n significant figures** of x if $|x - \hat{x}|$ has zeros in the first n decimal places counting from the leftmost nonzero (leading) digit of x , followed by a digit from 0 to 4.

$$x = 3.141592653$$

1) $\hat{x} = 3.14$

2) $\hat{x} = 3.14159$

3) $\hat{x} = 3.1415$

4) $\hat{x} = 3.1416$

\hat{x} has **n significant figures** of x if $|x - \hat{x}|$ has zeros in the first n decimal places counting from the leftmost nonzero (leading) digit of x , followed by a digit from 0 to 4.

So far, we can observe that $|x - \hat{x}| \leq 5 \times 10^{-n}$. Note that the exact number in this example can be written in the scientific notation form $x = q \times 10^0$. *What happens when the exponent is not zero?*

We use the relative error definition instead!

$$e_r = \frac{|x - \hat{x}|}{|x|}$$

Accurate to n significant digits means that you can trust a total of n digits. *Accurate digits* is a measure of relative error.

n is the number of accurate significant digits

Relative error: $error = \frac{|x_{exact} - x_{approx}|}{|x_{exact}|} \leq 5 \times 10^{-n}$

In general, we will use the rule-of-thumb:

$$error = \frac{|x_{exact} - x_{approx}|}{|x_{exact}|} \leq 10^{-n+1}$$

For example, if relative error is 10^{-2} then \hat{x} has at most _____ significant figures of x

After rounding, the resulting number has 5 accurate digits. What is the tightest estimate of the upper bound on my relative error?

A) 10^5

B) 10^{-5}

C) 10^4

D) 10^{-4}

Sources of Error

Main source of errors in numerical computation:

- **Rounding error:** occurs when digits in a decimal point ($1/3 = 0.3333\dots$) are lost (0.3333) due to a limit on the memory available for storing one numerical value.
- **Truncation error:** occurs when discrete values are used to approximate a mathematical expression (eg. the approximation $\sin(\theta) \approx \theta$ for small angles θ)

Let's first talk about plots...

- Power functions:

- Exponential functions:

Big-O notation

Complexity: Matrix-matrix multiplication

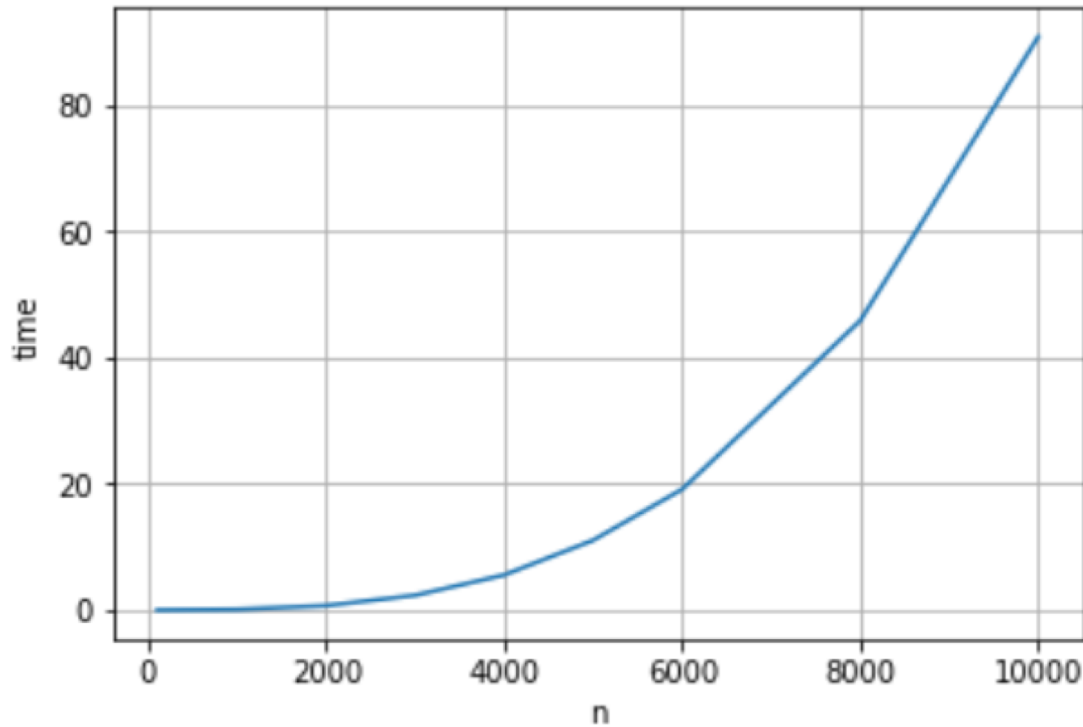

For a matrix with dimensions $n \times n$, the computational complexity can be represented by a power function:

$$time = c n^a$$

We could count the total number of operations to determine the value of the constants above, but instead, we will get an estimate using a numerical experiment where we perform several matrix-matrix multiplications for vary matrix sizes, and store the time to take to perform the operation.

For a matrix with dimensions $n \times n$, the computational complexity can be represented by a power function:

$$time = c n^a$$

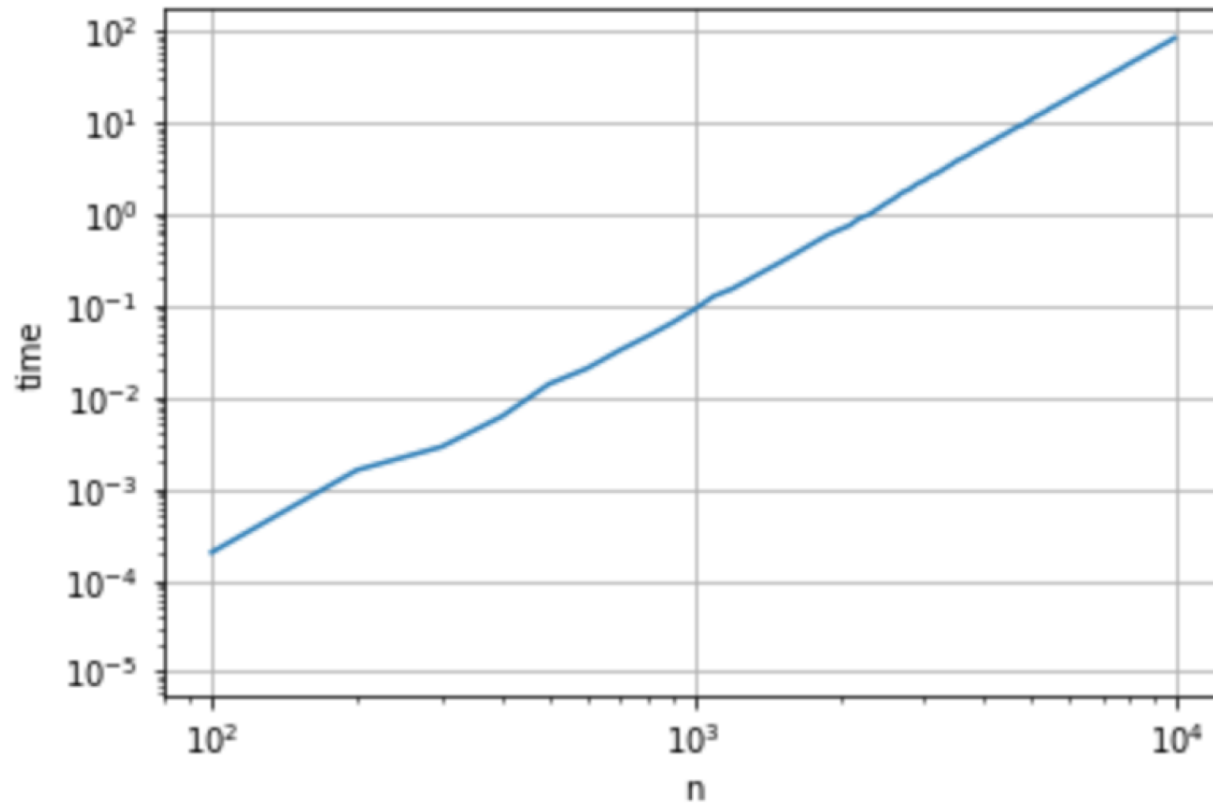

What type of plot will result in a straight line?

- A) semilog-x B) semilog-y C) log-log

Power functions are represented by straight lines in a log-log plot, where the coefficient a is determined by the slope of the line.

$$time = c n^a$$

Demo: Cost of Matrix-Matrix Multiplication

Instead of predicting time using $time = c n^a$, we can use the big-O notation to write

$$time = O(n^a)$$

where a can be obtained from the slope of the straight line.

For a matrix-matrix multiplication, what is the value of a ?

Demo: Cost of Matrix-Matrix Multiplication

As we mentioned previously, we can also get the complexity by counting the number of operations needed to perform the computation:

Big-Oh notation

Let f and g be two functions. Then

$$f(x) = O(g(x)) \text{ as } x \rightarrow \infty$$

If and only if there is a positive constant M such that for all sufficiently large values of x , the absolute value of $f(x)$ is at most multiplied by the absolute value of $g(x)$. In other words, there exists a value M and some x_0 such that:

$$|f(x)| \leq M |g(x)| \quad \forall x \geq x_0$$

Example:

Consider the function $f(x) = 2x^2 + 27x + 1000$

$$x \rightarrow \infty$$

Accuracy: approximating sine function

The sine function can be expressed as an infinite series:

$$f(x) = \sin(x) = x - \frac{x^3}{6} + \frac{x^5}{120} - \frac{x^7}{5040} + \dots$$

(we will discuss these approximations later)

Suppose we approximate $f(x)$ as $\tilde{f}(x) = x$

We can define the error as:

$$E = |f(x) - \tilde{f}(x)| = \left| -\frac{x^3}{6} + \frac{x^5}{120} - \frac{x^7}{5040} + \dots \right|$$

Or we can use the Big-O notation to say:

$$\mathbf{E = O(x^3)}$$

Big-Oh notation (continue)

Let f and g be two functions. Then

$$f(x) = O(g(x)) \text{ as } x \rightarrow a$$

If and only if there exists a value M and some δ such that:

$$|f(x)| \leq M |g(x)| \quad \forall x \text{ where } 0 < |x - a| < \delta$$

Same example...

Consider the function $f(x) = 2x^2 + 27x + 1000$

$$x \rightarrow 0$$

Clicker question

Suppose that the truncation error of a numerical method is given by the following function:

$$E(h) = 5h^2 + 3h$$

Which of the following functions are Oh-estimates of $E(h)$ as $h \rightarrow 0$

- 1) $O(5h^2)$
- 2) $O(h)$
- 3) $O(5h^2 + 3h)$
- 4) $O(h^2)$

Mark the correct answer:

- A) 1 and 2
- B) 2 and 3
- C) 2 and 4
- D) 3 and 4
- E) NOTA

Clicker question

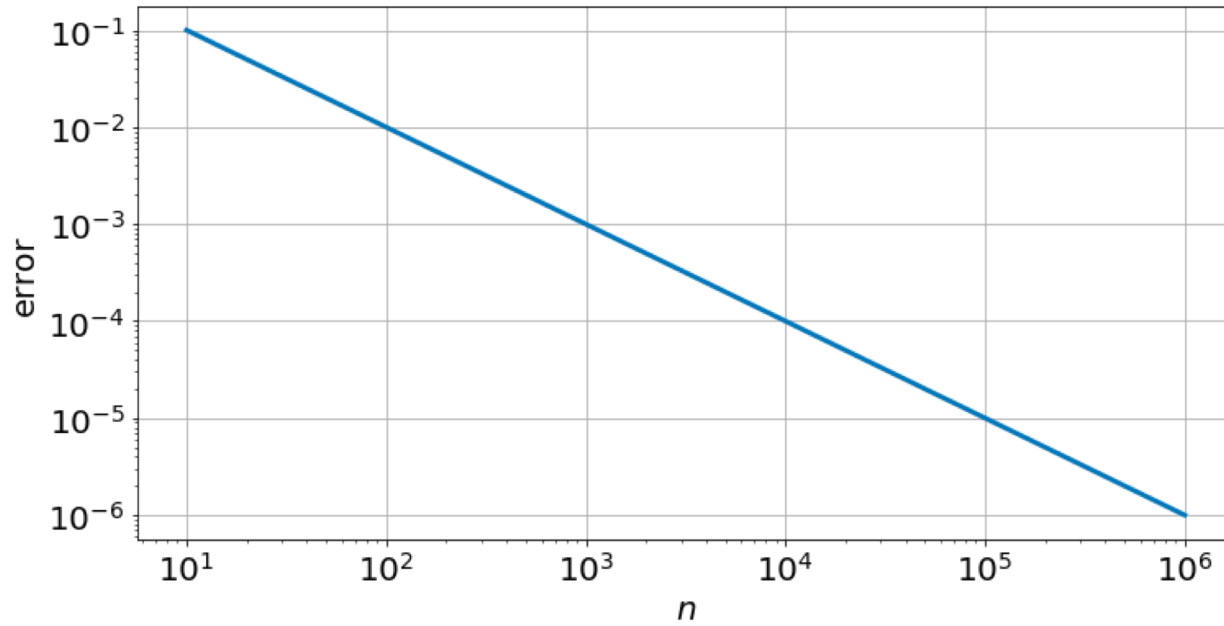

Suppose that the complexity of a numerical method is given by the following function:

$$c(n) = 5n^2 + 3n$$

Which of the following functions are Oh-estimates of $c(n)$ as $n \rightarrow \infty$

- | | |
|-------------------|------------------|
| 1) $O(5n^2 + 3n)$ | Mark the correct |
| 2) $O(n^2)$ | answer: |
| 3) $O(n^3)$ | A) 1,2,3 |
| 4) $O(n)$ | B) 1,2,3,4 |
| | C) 4 |
| | D) 3 |
| | E) NOTA |

Select the function that best represents the decay of the error as n increases

A) e^{-2n}

B) e^{-n}

C) n^{-1}

D) n^{-2}

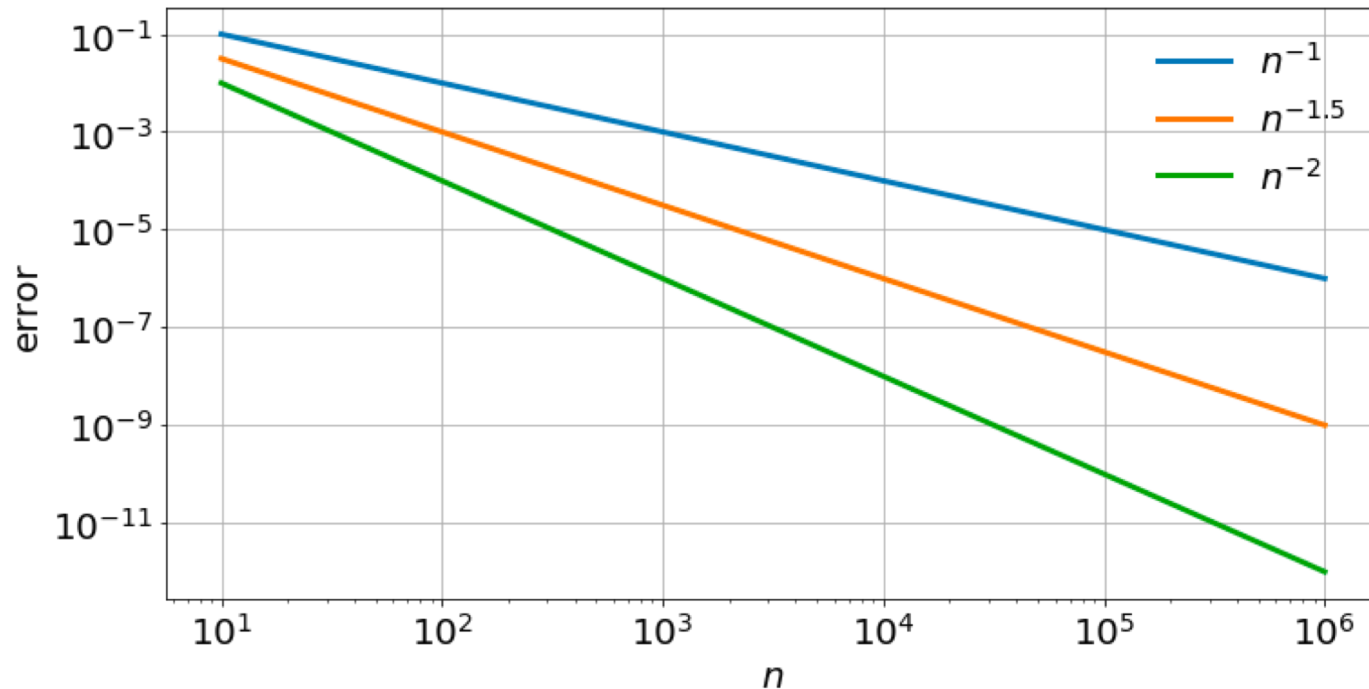

Rates of convergence

1) Algebraic convergence: $error \sim \frac{1}{n^\alpha}$ or $O\left(\frac{1}{n^\alpha}\right)$

Algebraic growth: $time \sim n^\alpha$ or $O(n^\alpha)$

α : Algebraic index of convergence

A sequence that grows or converges algebraically is a straight line in a log-log plot.

Rates of convergence

2) Exponential convergence: $error \sim e^{-\alpha n}$ or $O(e^{-\alpha n})$

Exponential growth: $time \sim e^{\alpha n}$ or $O(e^{\alpha n})$

A sequence that grows or converges exponentially is a straight line in a linear-log plot.

Rates of convergence

Exponential growth/convergence is much faster than algebraic growth/convergence.
