Greedy Algorithms
Lecture 19
Tuesday, November 7, 2017

What is a Greedy Algorithm?
No real consensus on a universal definition.

Greedy algorithms:
- make decision incrementally in small steps without backtracking
- decision at each step is based on improving local or current state in a myopic fashion without paying attention to the global situation
- decisions often based on some fixed and simple priority rules

Pros and Cons of Greedy Algorithms

Pros:
- Usually (too) easy to design greedy algorithms
- Easy to implement and often run fast since they are simple
- Several important cases where they are effective/optimal
- Lead to a first-cut heuristic when problem not well understood

Cons:
- Very often greedy algorithms don’t work. Easy to lull oneself into believing they work
- Many greedy algorithms possible for a problem and no structured way to find effective ones

CS 374: Every greedy algorithm needs a proof of correctness
Greedy Algorithm Types

Crude classification:
- **Non-adaptive:** fix some ordering of decisions a priori and stick with the order
- **Adaptive:** make decisions adaptively but greedily/locally at each step

Plan:
- See several examples
- Pick up some proof techniques

Part II

Scheduling Jobs to Minimize Average Waiting Time

The Problem

- **n** jobs \( J_1, J_2, \ldots, J_n \). \( J_i \) has non-negative processing time \( p_i \)
- One server/machine/person available to process jobs.
- Schedule/order jobs to min. total or average waiting time
- Waiting time of \( J_i \) in schedule \( \sigma \): sum of processing times of all jobs scheduled before \( J_i \)

<table>
<thead>
<tr>
<th>( J_1 )</th>
<th>( J_2 )</th>
<th>( J_3 )</th>
<th>( J_4 )</th>
<th>( J_5 )</th>
<th>( J_6 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>time</td>
<td>3</td>
<td>4</td>
<td>1</td>
<td>8</td>
<td>2</td>
</tr>
</tbody>
</table>

Example: schedule is \( J_1, J_2, J_3, J_4, J_5, J_6 \). Total waiting time is

\[ 0 + 3 + (3 + 4) + (3 + 4 + 1) + (3 + 4 + 1 + 8) + \ldots = \]

Optimal schedule: Shortest Job First. \( J_3, J_5, J_1, J_2, J_6, J_4 \).

Optimality of Shortest Job First (SJF)

Theorem

*Shortest Job First gives an optimum schedule for the problem of minimizing total waiting time.*

Proof strategy: exchange argument

Assume without loss of generality that job sorted in increasing order of processing time and hence \( p_1 \leq p_2 \leq \ldots \leq p_n \) and SJF order is \( J_1, J_2, \ldots, J_n \).
Inversions

Definition
A schedule $J_1, J_2, \ldots, J_n$ has an inversion if there are jobs $J_a$ and $J_b$ such that $S$ schedules $J_a$ before $J_b$, but $p_a > p_b$.

Claim
If a schedule has an inversion then there is an inversion between two adjacently scheduled jobs.

Proof: exercise.

Proof of optimality of SJF

Recall SJF order is $J_1, J_2, \ldots, J_n$.
- Let $J_{i_1}, J_{i_2}, \ldots, J_{i_n}$ be an optimum schedule with fewest inversions.
- If schedule has no inversions then it is identical to SJF schedule and we are done.
- Otherwise there is an $1 \leq \ell < n$ such that $i_\ell > i_{\ell + 1}$ since schedule has inversion among two adjacently scheduled jobs.

Claim
The schedule obtained from $J_{i_1}, J_{i_2}, \ldots, J_{i_n}$ by exchanging/swapping positions of jobs $J_{i_\ell}$ and $J_{i_{\ell + 1}}$ is also optimal and has one fewer inversion.

Assuming claim we obtain a contradiction and hence optimum schedule with fewest inversions must be the SJF schedule.

A Weighted Version

- $n$ jobs $J_1, J_2, \ldots, J_n$. $J_i$ has non-negative processing time $p_i$ and a non-negative weight $w_i$.
- One server/machine/person available to process jobs.
- Schedule/order the jobs to minimize total or average waiting time.
- Waiting time of $J_i$ in schedule $\sigma$: sum of processing times of all jobs scheduled before $J_i$.
- Goal: minimize total weighted waiting time.

Part III

Scheduling to Minimize Lateness

Sariel Har-Peled (UIUC)

CS374 13

Fall 2017 13 / 42

Given jobs $J_1, J_2, \ldots, J_n$ with deadlines and processing times to be scheduled on a single resource.

If a job $i$ starts at time $s_i$ then it will finish at time $f_i = s_i + t_i$, where $t_i$ is its processing time. $d_i$: deadline.

The lateness of a job is $\ell_i = \max(0, f_i - d_i)$.

Schedule all jobs such that $L = \max \ell_i$ is minimized.

Scheduling to Minimize Lateness

Greedy Template

Initially $R$ is the set of all requests

curr_time = 0
max_lateness = 0

while $R$ is not empty do
choose $i \in R$
curr_time = curr_time + $t_i$
if (curr_time > $d_i$) then
max_lateness = max(curr_time - $d_i$, max_lateness)

return max_lateness

Main task: Decide the order in which to process jobs in $R$

Three Algorithms

- Shortest job first — sort according to $t_i$.
- Shortest slack first — sort according to $d_i - t_i$.
- EDF = Earliest deadline first — sort according to $d_i$.

Counter examples for first two: exercise
Earliest Deadline First

**Theorem**

*Greedy with EDF rule minimizes maximum lateness.*

Proof via an exchange argument.

Idle time: time during which machine is not working.

**Lemma**

*If there is a feasible schedule then there is one with no idle time before all jobs are finished.*

---

Proof sketch of Optimality of EDP

- Let $S$ be an optimum schedule with smallest number of inversions.
- If $S$ has no inversions then this is same as EDF and we are done.
- Else $S$ has two adjacent jobs $i$ and $j$ with $d_i > d_j$.
- Swap positions of $i$ and $j$ to obtain a new schedule $S'$

**Claim**

*Maximum lateness of $S'$ is no more than that of $S$. And $S'$ has strictly fewer inversions than $S$."

---

Inversions

* = Earliest Deadline First

Assume jobs are sorted such that $d_1 \leq d_2 \leq \ldots \leq d_n$. Hence EDF schedules them in this order.

**Definition**

*A schedule $S$ is said to have an inversion if there are jobs $i$ and $j$ such that $S$ schedules $i$ before $j$, but $d_i > d_j$.*

**Claim**

*If a schedule $S$ has an inversion then there is an inversion between two adjacently scheduled jobs.*

Proof: exercise.

---

Part IV

Maximum Weight Subset of Elements: Cardinality and Beyond
Picking \( k \) elements to maximize total weight

- Given \( n \) items each with non-negative weights/profits and integer \( 1 \leq k \leq n \).
- Goal: pick \( k \) elements to maximize total weight of items picked.

<table>
<thead>
<tr>
<th></th>
<th>( e_1 )</th>
<th>( e_2 )</th>
<th>( e_3 )</th>
<th>( e_4 )</th>
<th>( e_5 )</th>
<th>( e_6 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>weight</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>4</td>
<td>3</td>
<td>2</td>
</tr>
</tbody>
</table>

\( k = 2 \):
\( k = 3 \):
\( k = 4 \):

Greedy Template

\[
N \text{ is the set of all elements } X \leftarrow \emptyset
\]
\( (* X \) will store all the elements that will be picked *)
\[
\text{while } |X| < k \text{ and } N \text{ is not empty do}
\]
\[
\text{choose } e_j \in N \text{ of maximum weight}
\]
\[
\text{add } e_j \text{ to } X
\]
\[
\text{remove } e_j \text{ from } N
\]
\[
\text{return the set } X
\]

Remark: One can rephrase algorithm simply as sorting elements in decreasing weight order and picking the top \( k \) elements but the above template generalizes to other settings a bit more easily.

Theorem

Greedy is optimal for picking \( k \) elements of maximum weight.

A more interesting problem

- Given \( n \) items \( N = \{e_1, e_2, \ldots, e_n\} \). Each item \( e_i \) has a non-negative weight \( w_i \).
- Items partitioned into \( h \) sets \( N_1, N_2, \ldots, N_h \). Think of each item having one of \( h \) colors.
- Given integers \( k_1, k_2, \ldots, k_h \) and another integer \( k \)
- Goal: pick \( k \) elements such that no more than \( k_i \) from \( N_i \) to maximize total weight of items picked.

<table>
<thead>
<tr>
<th></th>
<th>( e_1 )</th>
<th>( e_2 )</th>
<th>( e_3 )</th>
<th>( e_4 )</th>
<th>( e_5 )</th>
<th>( e_6 )</th>
<th>( e_7 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>weight</td>
<td>9</td>
<td>5</td>
<td>4</td>
<td>7</td>
<td>5</td>
<td>2</td>
<td>1</td>
</tr>
</tbody>
</table>

\( N_1 = \{e_1, e_2, e_3\} \), \( N_2 = \{e_4, e_5\} \), \( N_3 = \{e_6, e_7\} \)
\( k = 4 \), \( k_1 = 2 \), \( k_2 = 1 \), \( k_3 = 2 \)

Greedy Template

\[
N \text{ is the set of all elements } X \leftarrow \emptyset
\]
\( (* X \) will store all the elements that will be picked *)
\[
\text{while } N \text{ is not empty do}
\]
\[
\text{if } N' = \emptyset \text{ then break}
\]
\[
\text{choose } e_j \in N' \text{ of maximum weight}
\]
\[
\text{add } e_j \text{ to } X
\]
\[
\text{remove } e_j \text{ from } N
\]
\[
\text{return the set } X
\]

Theorem

Greedy is optimal for the problem on previous slide.

Proof: exercise after class.

Special case of general phenomenon of Greedy working for maximum weight independent set in a matroid. Beyond scope of course.
Part V

Interval Scheduling

Greedy Template

\( R \) is the set of all requests
\( X \leftarrow \emptyset \) (* \( X \) will store all the jobs that will be scheduled *)
while \( R \) is not empty do
  choose \( i \in R \)
  add \( i \) to \( X \)
  remove from \( R \) all requests that overlap with \( i \)
return the set \( X \)

Main task: Decide the order in which to process requests in \( R \)

Earliest Start Time

Process jobs in the order of their starting times, beginning with those that start earliest.
Smallest Processing Time

Process jobs in the order of processing time, starting with jobs that require the shortest processing.

Fewest Conflicts

Process jobs in that have the fewest “conflicts” first.

Earliest Finish Time

Process jobs in the order of their finishing times, beginning with those that finish earliest.

Optimal Greedy Algorithm

Let $R$ be the set of all requests.

\[ X \leftarrow \emptyset \quad \text{(} X \text{ stores the jobs that will be scheduled *)} \]

while $R$ is not empty

\[ \text{choose } i \in R \text{ such that finishing time of } i \text{ is smallest} \]

add $i$ to $X$

remove from $R$ all requests that overlap with $i$

return $X$

Theorem

The greedy algorithm that picks jobs in the order of their finishing times is optimal.
Proving Optimality

- **Correctness:** Clearly the algorithm returns a set of jobs that does not have any conflicts.
- For a set of requests $R$, let $O$ be an optimal set and let $X$ be the set returned by the greedy algorithm. Then $O = X$? Not likely!

<table>
<thead>
<tr>
<th>O</th>
<th>X</th>
</tr>
</thead>
<tbody>
<tr>
<td>$i_1$</td>
<td>$i_2$</td>
</tr>
<tr>
<td>$j_1$</td>
<td>$j_2$</td>
</tr>
</tbody>
</table>

Proof of Optimality: Key Lemma

**Lemma**

Let $i_1$ be first interval picked by Greedy. There exists an optimum solution that contains $i_1$.

**Proof.**

Let $O$ be an arbitrary optimum solution. If $i_1 \in O$ we are done.

**Claim:** If $i_1 \not\in O$ then there is exactly one interval $j_1 \in O$ that conflicts with $i_1$. (proof later)

- Form a new set $O'$ by removing $j_1$ from $O$ and adding $i_1$, that is $O' = (O - \{j_1\}) \cup \{i_1\}$.
- From claim, $O'$ is a feasible solution (no conflicts).
- Since $|O'| = |O|$, $O'$ is also an optimum solution and it contains $i_1$.

Proof of Claim

**Claim**

If $i_1 \not\in O$, there is exactly one interval $j_1 \in O$ that conflicts with $i_1$.

**Proof.**

- If no $j \in O$ conflicts with $i_1$ then $O$ is not optimal!
- Suppose $j_1, j_2 \in O$ such that $j_1 \neq j_2$ and both $j_1$ and $j_2$ conflict with $i_1$.
- Since $i_1$ has earliest finish time, $j_1$ and $i_1$ overlap at $f(i_1)$.
- For same reason $j_2$ also overlaps with $i_1$ at $f(i_1)$.
- Implies that $j_1, j_2$ overlap at $f(i_1)$ but intervals in $O$ cannot overlap.

See figure in next slide.

Figure for proof of Claim

**Figure:** Since $i_1$ has the earliest finish time, any interval that conflicts with it does so at $f(i_1)$. This implies $j_1$ and $j_2$ conflict.
Proof of Optimality of Earliest Finish Time First

Proof by Induction on number of intervals.

**Base Case:** \( n = 1 \). Trivial since Greedy picks one interval.

**Induction Step:** Assume theorem holds for \( i < n \).

Let \( I \) be an instance with \( n \) intervals

\[ I' : I \text{ with } i_1 \text{ and all intervals that overlap with } i_1 \text{ removed} \]

\[ G(I), G(I') : \text{Solution produced by Greedy on } I \text{ and } I' \]

From Lemma, there is an optimum solution \( O \) to \( I \) and \( i_1 \in O \).

Let \( O' = O - \{i_1\} \). \( O' \) is a solution to \( I' \).

\[
|G(I)| = 1 + |G(I')| \quad \text{(from Greedy description)}
\]

\[
\geq 1 + |O'| \quad \text{(By induction, } G(I') \text{ is optimum for } I')
\]

\[
= |O|
\]

---

Implementation and Running Time

Initially \( R \) is the set of all requests

\[
X \leftarrow \emptyset \quad \text{(* } X \text{ stores the jobs that will be scheduled * )}
\]

while \( R \) is not empty

choose \( i \in R \) such that finishing time of \( i \) is least

if \( i \) does not overlap with requests in \( X \)

add \( i \) to \( X \)

remove \( i \) from \( R \)

return the set \( X \)

- Presort all requests based on finishing time. \( O(n \log n) \) time
- Now choosing least finishing time is \( O(1) \)
- Keep track of the finishing time of the last request added to \( A \).
- Then check if starting time of \( i \) later than that
- Thus, checking non-overlapping is \( O(1) \)
- Total time \( O(n \log n + n ) = O(n \log n) \)

---

Comments

1. Interesting Exercise: smallest interval first picks at least half the optimum number of intervals.
2. All requests need not be known at the beginning. Such *online* algorithms are a subject of research

---

Weighted Interval Scheduling

Suppose we are given \( n \) jobs. Each job \( i \) has a start time \( s_i \), a finish time \( f_i \), and a weight \( w_i \). We would like to find a set \( S \) of compatible jobs whose total weight is maximized. Which of the following greedy algorithms finds the optimum schedule?

(A) Earliest start time first.

(B) Earliest finish time fist.

(C) Highest weight first.

(D) None of the above.

(E) IDK.

Weighted problem can be solved via dynamic programming. See notes.
Greedy Analysis: Overview

- **Greedy’s first step leads to an optimum solution.** Show that there is an optimum solution leading from the first step of Greedy and then use induction. Example, Interval Scheduling.
- **Greedy algorithm stays ahead.** Show that after each step the solution of the greedy algorithm is at least as good as the solution of any other algorithm. Example, Interval scheduling.
- **Structural property of solution.** Observe some structural bound of every solution to the problem, and show that greedy algorithm achieves this bound. Example, Interval Partitioning (see Kleinberg-Tardos book).
- **Exchange argument.** Gradually transform any optimal solution to the one produced by the greedy algorithm, without hurting its optimality. Example, Minimizing lateness.

Takeaway Points

- **Greedy algorithms come naturally but often are incorrect.** A proof of correctness is an absolute necessity.
- **Exchange arguments are often the key proof ingredient.** Focus on why the first step of the algorithm is correct: need to show that there is an optimum/correct solution with the first step of the algorithm.
- **Thinking about correctness is also a good way to figure out which of the many greedy strategies is likely to work.**
