1. Snakes and Ladders is played on an $n \times n$ grid of squares, numbered consecutively from 1 to $n^2$, starting in the bottom left corner and proceeding row by row from bottom to top, with rows alternating to the left and right. Certain pairs of squares, always in different rows, are connected by either “snakes” (leading down) or “ladders” (leading up). Each square can be an endpoint of at most one snake or ladder.

You start with a token in cell 1, in the bottom left corner. In each move, you advance your token up to $k$ positions, for some fixed constant $k$ (typically 6). If the token ends the move at the top end of a snake, you must slide the token down to the bottom of that snake. If the token ends the move at the bottom end of a ladder, you may move the token up to the top of that ladder.

Describe and analyze an algorithm to compute the smallest number of moves required for a token to move from the first square to the last square on an $n \times n$ Snakes and Ladders board.

**Solution:** We reduce to a shortest-path problem in a directed graph $G = (V, E)$ as follows:

- The vertices of $G$ correspond to cells on the board, identified by integers 1 to $n^2$.
- The edges of $G$ correspond to legal moves. From each cell there are at most $2k$ possible moves: for each integer $i$ from 1 to $k$, we can move forward $i$ spaces, and then if we are at the bottom of a ladder, we can either move to the top of that ladder or not. (If moving $i$ spaces forward puts us at the top of a snake, we must move to the bottom of the snake.) Edges are directed.
- We do not need to associate additional values with the vertices or edges.
- We need to find the shortest path from vertex 1 to vertex $n^2$.
- We can solve this problem using breadth-first search.
- The algorithm runs in $O(V + E) = O(n^2 + 2kn^2) = O(kn^2)$ time.

2. Let $G$ be a connected undirected graph. Suppose we start with two coins on two arbitrarily chosen vertices of $G$. At every step, each coin must move to an adjacent vertex. Describe and analyze an algorithm to compute the minimum number of steps to reach a configuration where both coins are on the same vertex, or to report correctly that no such configuration is reachable. The input to your algorithm consists of a graph $G = (V, E)$ and two vertices $u, v \in V$ (which may or may not be distinct).

**Solution (product construction):** Let $G = (V, E)$ denote the input graph, and let $s$ and $t$ denote the initial locations of the two coins. We reduce to a shortest-path problem in an undirected graph $G' = (V', E')$ as follows:

- $V' = V \times V = \{(u, v) \mid u \in V \text{ and } v \in V\}$; the vertices of $G'$ correspond to possible placements of the two coins.
- $E' = \{(u, v)(u', v') \mid uu' \in E \text{ and } vv' \in E\}$. The edges of $G'$ correspond to legal
moves by the two coins. Edges are undirected, because any move by the two coins can be reversed.

• We do not need to associate additional values with the vertices or edges.
• We need to find the shortest-path distance from vertex \((s, t)\) to any vertex of the form \((v, v)\).
• First we compute the shortest-path distance from \((s, t)\) to every vertex in \(G'\) that is reachable from \((s, t)\) using breadth-first search. Then a simple for-loop over the vertices of the input graph \(G\) finds the minimum distance to any marked vertex of the form \((v, v)\). In particular, if no vertex \((v, v)\) is reachable from \((s, t)\), then no vertex \((v, v)\) will be marked by the breadth-first search, and so the algorithm will correctly report \(\min \emptyset = \infty\).
• The resulting algorithm runs in \(O(V' + E') = O(V^2 + E^2)\) time.

Solution (parity construction): Let \(G = (V, E)\) denote the input graph, and let \(s\) and \(t\) denote the initial locations of the two coins. Any sequence of \(k\) moves that bring the two coins to a common vertex \(x\) defines a walk of length \(2k\) from \(s\) to \(t\) with midpoint \(x\), and vice versa. Thus, we are looking for the shortest walk from \(s\) to \(t\) with even length. We reduce to a standard shortest-path problem in a new graph \(G' = (V', E')\) as follows:

- \(V' = V \times \{0, 1\} = \{(v, b) \mid b \in V \text{ and } b \in \{0, 1\}\}\).
- \(E' = \{(u, b)(v, 1 - b) \mid uv \in E \text{ and } b \in \{0, 1\}\}\). Edges in \(G'\) are undirected, because edges in the original graph \(G\) are undirected.
  
  For any walk \(v_0 \rightarrow v_1 \rightarrow v_2 \rightarrow \cdots \rightarrow v_\ell\) in \(G\), there is a corresponding walk \((v_0, 0) \rightarrow (v_1, 1) \rightarrow (v_2, 0) \rightarrow \cdots \rightarrow (v_\ell, \ell \mod 2)\) in \(G'\). Thus, every even-length walk from \(s\) to \(t\) in \(G\) corresponds to a walk from \((s, 0)\) to \((t, 0)\) in \(G'\) and vice versa.

- We do not need to associate additional values with the vertices or edges.
- We need to find the shortest-path distance in \(G'\) from vertex \((s, 0)\) to \((t, 0)\).
- We can compute this shortest-path distance using breadth-first search starting at \((s, 0)\). In particular, if there is no even-length path from \(s\) to \(t\) in \(G\), the breadth-first search will not mark \((t, 0)\).
- The resulting algorithm runs in \(O(V' + E') = O(V + E)\) time.
Harder problem to think about later:

3. Let $G$ be an undirected graph. Suppose we start with 374 coins on 374 arbitrarily chosen vertices of $G$. At every step, each coin must move to an adjacent vertex. Describe and analyze an efficient algorithm to compute the minimum number of steps to reach a configuration where all 374 coins are on the same vertex, or to report correctly that no such configuration is reachable. The input to your algorithm consists of a graph $G = (V,E)$ and starting vertices $s_1, s_2, \ldots, s_{374}$ (which may or may not be distinct).

Solution (product construction): We reduce to a shortest-path problem in an undirected graph $G' = (V',E')$ as follows:

- $V' = V^{374} = \overline{V \times V \times \cdots \times V} = \{(v_1, v_2, \ldots, v_{374}) \mid v_i \in V \text{ for all } i\}$; the vertices of $G'$ correspond to possible placements of the 374 coins.
- $E' = \{(u_1, u_2, \ldots, u_{374})(v_1, v_2, \ldots, v_{374}) \mid u_i v_i \in E \text{ for all } i\}$. The edges of $G'$ correspond to legal moves by the 374 coins. Edges are undirected, because any move by the two coins can be reversed.
- We do not need to associate additional values with the vertices or edges.
- We need to find the shortest-path distance from $s = (s_1, s_2, \ldots, s_{374})$ to any vertex of the form $(v, v, \ldots, v)$.
- First we compute the shortest-path distance from $s$ to every vertex in $G'$ that is reachable from $s$ using breadth-first search. Then a simple for-loop over the vertices of the input graph $G$ finds the minimum distance to any marked vertex of the form $(v, v, \ldots, v)$. In particular, if no vertex $(v, v, \ldots, v)$ is reachable from $s$, then no vertex $(v, v, \ldots, v)$ will be marked by the breadth-first search, and so the algorithm will correctly report $\min \emptyset = \infty$.
- The resulting algorithm runs in $O(V' + E') = O(V^{374} + E^{374})$ time. Oof.

Solution (parity construction): I claim that (1) there is a sequence of $k$ steps that move all coins to some target vertex $t$ if and only if (2) for each vertex $i$, there is a walk of length $k_i$ from starting vertex $s_i$ to $t$, such that $k = \max_i k_i$ and either all $k_i$ are even or all $k_i$ are odd.

- The implication (1) $\implies$ (2) follows immediately by setting $k_i = k$ for all $i$.
- Any walk of length $\ell$ can be turned into a walk of length $\ell + 2j$ with the same endpoints by repeating an edge, and therefore into a walk of length $\ell + 2j$ for any integer $j \geq 0$. The implication (2) $\implies$ (1) follows immediately.

Now for any vertex $v$ and any index $i$, we define two integers:

- $\text{deven}(s_i, v)$ is the length of the shortest even-length walk from $s_i$ to $v$ (or $\infty$ if there is no such walk).
- $\text{dodd}(s_i, v)$ is the length of the shortest odd-length walk from $s_i$ to $v$ (or $\infty$ if there is no such walk).
• \( \text{MinSteps}(v) \) is the minimum number of steps required to move all coins to \( v \). My earlier claim implies that

\[
\text{MinSteps}(v) = \min \left\{ \max_i \text{deven}(s_i, v), \max_i \text{dodd}(s_i, v) \right\}
\]

We need to compute \( \min \{\text{MinSteps}(v) \mid v \in V\} \).

Consider the unweighted undirected graph \( G' = (V', E') \) where \( V' = V \times \{0, 1\} \) and \( E' = \{(u, 0)(v, 1) \mid uv \in E\} \cup \{(u, 1)(v, 0) \mid uv \in E\} \). We immediately have

\[
deven(s_i, v) = d'(s_i, 0, (v, 0)) \quad \text{and} \quad \text{dodd}(s_i, v) = d'(s_i, 0, (v, 1)),
\]

where \( d'(u', v') \) is the shortest-path distance from \( u' \) to \( v' \) in \( G' \). Thus, we can compute \( \text{deven}(s_i, v) \) and \( \text{dodd}(s_i, v) \) for every vertex \( v \in V \) and every index \( i \) by running 374 breadth-first searches in \( G' \), each starting at some vertex \( (s_i, 0) \), in total \( 374 \times O(V' + E') = O(V + E) \) time. After computing these distances, we can easily compute \( \min \{\text{MinSteps}(v) \mid v \in V\} \) in \( O(V) \) time by brute force, because \( 374 = O(1) \).

Altogether, our algorithm runs in \( O(V + E) \) time. ■
