But the Lord came down to see the city and the tower the people were building. The Lord said, “If as one people speaking the same language they have begun to do this, then nothing they plan to do will be impossible for them. Come, let us go down and confuse their language so they will not understand each other.”

— Genesis 11:6–7 (New International Version)

Soyez réglé dans votre vie et ordinaire comme un bourgeois, afin d’être violent et original dans vos œuvres.
[Be regular and orderly in your life like a bourgeois, so that you may be violent and original in your work.]

— Gustave Flaubert, in a letter to Gertrude Tennant (December 25, 1876)

Some people, when confronted with a problem, think “I know, I’ll use regular expressions.” Now they have two problems.

— Jamie Zawinski, alt.religion.emacs (August 12, 1997)

As far as I am aware this pronunciation is incorrect in all known languages.

— Kenneth Kleene, describing his father Stephen’s pronunciation of his last name

2 Regular Languages

2.1 Languages

A formal language (or just a language) is a set of strings over some finite alphabet \( \Sigma \), or equivalently, an arbitrary subset of \( \Sigma^* \). For example, each of the following sets is a language:

- The empty set \( \emptyset \).
- The set \( \{ \epsilon \} \).
- The set \( \{ 0, 1 \}^* \).
- The set \( \{ \text{THERE}, \text{OXFORD}, \text{ENGLISH}, \text{DICTIONARY} \} \).
- The set of all subsequences of \( \text{THERE} \circ \text{OXFORD} \circ \text{ENGLISH} \circ \text{DICTIONARY} \).
- The set of all words in The Oxford English Dictionary.
- The set of all strings in \( \{ 0, 1 \}^* \) with an odd number of 1s.
- The set of all strings in \( \{ 0, 1 \}^* \) that represent a prime number in base 13.
- The set of all sequences of turns that solve the Rubik’s cube (starting in some fixed configuration)
- The set of all python programs that print “Hello World!”

As a notational convention, I will always use italic upper-case letters (usually \( L \), but also \( A, B, C, \) and so on) to represent languages.

Formal languages are not “languages” in the same sense that English, Klingon, and Python are “languages”. Strings in a formal language do not necessarily carry any “meaning”, nor are they necessarily assembled into larger units (“sentences” or “paragraphs” or “packages”) according to some “grammar”.

¹The empty set symbol \( \emptyset \) was introduced in 1939 by André Weil, as a member of the pseudonymous mathematical collective Nicholai Bourbaki. The symbol derives from the Norwegian letter Ø, which pronounced like a German ö or a sound of disgust, and not from the Greek letter \( \phi \). Calling the empty set “fie” or “fee” makes the baby Jesus cry.
It is very important to distinguish between three “empty” objects. Many beginning students have trouble keeping these straight.

- $\emptyset$ is the empty language, which is a set containing zero strings. $\emptyset$ is not a string.
- $\{\epsilon\}$ is a language containing exactly one string, which has length zero. $\{\epsilon\}$ is not empty, and it is not a string.
- $\epsilon$ is the empty string, which is a sequence of length zero. $\epsilon$ is not a language.

2.2 Building Languages

Languages can be combined and manipulated just like any other sets. Thus, if $A$ and $B$ are languages over $\Sigma$, then their union $A \cup B$, intersection $A \cap B$, difference $A \setminus B$, and symmetric difference $A \oplus B$ are also languages over $\Sigma$, as is the complement $\overline{A} := \Sigma^* \setminus A$. However, there are two more useful operators that are specific to sets of strings.

The concatenation of two languages $A$ and $B$, again denoted $A \cdot B$ or just $AB$, is the set of all strings obtained by concatenating an arbitrary string in $A$ with an arbitrary string in $B$:

$$A \cdot B := \{xy \mid x \in A \text{ and } y \in B\}.$$  

For example, if $A = \{\text{HOCUS, ABRACA}\}$ and $B = \{\text{POCUS, DABRA}\}$, then

$$A \cdot B = \{\text{HOCUSPOCUS, ABRACAPOCUS, HOCUSDABRA, ABRACADABRA}\}.$$

In particular, for every language $A$, we have

$$\emptyset \cdot A = A \cdot \emptyset = \emptyset \quad \text{and} \quad \{\epsilon\} \cdot A = A \cdot \{\epsilon\} = A.$$

The Kleene closure or Kleene star$^2$ of a language $L$, denoted $L^*$, is the set of all strings obtained by concatenating a sequence of zero or more strings from $L$. For example, $\{0, 11\}^* = \{\epsilon, 0, 00, 11, 000, 011, 110, 0000, 0011, 0110, 1100, 1111, 00000, 00011, 011110011011, \ldots\}$. More formally, $L^*$ is defined recursively as the set of all strings $w$ such that either

- $w = \epsilon$, or
- $w = xy$, for some strings $x \in L$ and $y \in L^*$.

This definition immediately implies that

$$\emptyset^* = \{\epsilon\}^* = \{\epsilon\}.$$

For any other language $L$, the Kleene closure $L^*$ is infinite and contains arbitrarily long (but finite!) strings. Equivalently, $L^*$ can also be defined as the smallest superset of $L$ that contains the empty string $\epsilon$ and is closed under concatenation (hence “closure”). The set of all strings $\Sigma^*$ is, just as the notation suggests, the Kleene closure of the alphabet $\Sigma$ (where each symbol is viewed as a string of length 1).

A useful variant of the Kleene closure operator is the Kleene plus, defined as $L^+ := L \cdot L^*$. Thus, $L^+$ is the set of all strings obtained by concatenating a sequence of one or more strings from $L$.

The following identities, which we state here without (easy) proofs, are useful for designing, simplifying, and understanding languages.

$^2$named after logician Stephen Cole Kleene, who actually pronounced his last name “clay-knee”, not “clean” or “cleanie” or “claynuh” or “dimaggio”.

2
Lemma 2.1. The following identities hold for all languages $A$, $B$, and $C$:

(a) $\emptyset A = A \emptyset = \emptyset$.
(b) $\epsilon A = A \epsilon = A$.
(c) $A + B = B + A$.
(d) $(A + B) + C = A + (B + C)$.
(e) $(AB)C = A(BC)$.
(f) $A(B + C) = AB + AC$.

Lemma 2.2. The following identities hold for every language $L$:

(a) $L^* = \epsilon + L^+ = L^+ L^* = (L + \epsilon)^* = (L \setminus \epsilon)^* = \epsilon + L^+ L^*$.
(b) $L^+ = L^* \setminus \epsilon = LL^* = L^+ L^* = L^+ L^* = L + L^+ L^*$.
(c) $L^+ = L^*$ if and only if $\epsilon \in L$.

Lemma 2.3 (Arden’s Rule). For any languages $A$, $B$, and $L$ such that $L = AL + B$, we have $A^* B \subseteq L$. Moreover, if $A$ does not contain the empty string, then $L = AL + B$ if and only if $L = A^* B$.

2.3 Regular Languages and Regular Expressions

Intuitively, a language is regular if it can be constructed from individual strings using any combination of union, concatenation, and unbounded repetition. More formally, a language $L$ is regular if and only if it satisfies one of the following (recursive) conditions:

- $L$ is empty;
- $L$ contains a single string (which could be the empty string $\epsilon$);
- $L$ is the union of two regular languages;
- $L$ is the concatenation of two regular languages; or
- $L$ is the Kleene closure of a regular language.

Regular languages are normally described using a compact notation called regular expressions, which omit braces around one-string sets, use $+$ to represent union instead of $\cup$, and juxtapose subexpressions to represent concatenation instead of using an explicit operator $\cdot$. By convention, in the absence of parentheses, the $^*$ operator has highest precedence, followed by the (implicit) concatenation operator, followed by $+$.

For example, the regular expression $10^*$ is shorthand for the language $\{1\} \cdot \{0\}^*$ (containing all strings consisting of a 1 followed by zero or more 0s), and not the language $\{10\}^*$ (containing all strings of even length that start with 1 and alternate between 1 and 0). As a larger example, the regular expression

$$0 + 0^* 1 (10^* 1 + 01^* 0)^* 10^*$$

represents the language

$$\{0\} \cup \left(\{0\}^* \cdot \{1\} \cdot ((\{1\} \cdot \{0\}^* \cdot \{1\}) \cup (\{0\} \cdot \{1\}^* \cdot \{0\}))^* \cdot \{1\} \cdot \{0\}^* \right).$$

Most of the time we do not distinguish between regular expressions and the languages they represent, for the same reason that we do not normally distinguish between the arithmetic
expression “2+2” and the integer 4, or the symbol π and the area of the unit circle. However, we sometimes need to refer to regular expressions themselves as strings. In those circumstances, we write \( L(R) \) to denote the language represented by the regular expression \( R \). String \( w \) matches regular expression \( R \) if and only if \( w \in L(R) \).

Here are several more examples of regular expressions and the languages they represent.

- \( 0^* \) — the set of all strings of 0s, including the empty string.
- \( 00000^* \) — the set of all strings consisting of at least four 0s.
- \( (00000)^* \) — the set of all strings of 0s whose length is a multiple of 5.
- \( (\epsilon + 1)(01)^*(\epsilon + 0) \) — the set of all strings of alternating 0s and 1s, or equivalently, the set of all binary strings that do not contain the substrings 00 or 11.
- \( ((\epsilon + 0 + 00 + 000)1)^*(\epsilon + 0 + 00 + 000) \) — the set of all binary strings that do not contain the substring 0000.
- \( ((0 + 1)(0 + 1))^* \) — the set of all binary strings whose length is even.
- \( 1^*(01^*01^*)^* \) — the set of all binary strings with an even number of 0s.
- \( 0 + 1(0 + 1)^*00 \) — the set of all non-negative binary numerals divisible by 4 and with no redundant leading 0s.
- \( 0 + 0*1(10*1 + 01*0)^*10^* \) — the set of all non-negative binary numerals divisible by 3, possibly with redundant leading 0s.

The last example should not be obvious. It is straightforward, but rather tedious, to prove by induction that every string in \( 0 + 0^*1(10^*1 + 01^*0)^*10^* \) is the binary representation of a non-negative multiple of 3. It is similarly straightforward, and similarly tedious, to prove that the binary representation of every non-negative multiple of 3 matches this regular expression. In a later note, we will see a systematic method for deriving regular expressions for some languages that avoids (or more accurately, automates) this tedium.

Two regular expressions \( R \) and \( R' \) are equivalent if they describe the same language; for example, the regular expressions \( (0 + 1)^* \) and \( (1 + 0)^* \) are equivalent, because the union operator is commutative. Almost every regular language can be represented by infinitely many distinct but equivalent regular expressions, even if we ignore ultimately trivial equivalences like \( L = (L\emptyset)^*L\epsilon + \emptyset \).

2.4 Things What Ain’t Regular Expressions

Many computing environments and programming languages support patterns called regexen (singular regex, pluralized like ox) that are considerably more general and powerful than regular expressions. Regexen include special symbols representing negation, character classes (for example, upper-case letters, or digits), contiguous ranges of characters, line and word boundaries, limited repetition (as opposed to the unlimited repetition allowed by \(^*\)), back-references to earlier subexpressions, and even local variables. Despite its obvious etymology, a regex is not necessarily a regular expression, and it does not necessarily describe a regular language!\(^3\)

\(^3\)However, regexen are not all-powerful, either; see http://stackoverflow.com/a/1732454/775369.
Another type of pattern that is often confused with regular expression are *globs*, which are patterns used in most Unix shells and some scripting languages to represent sets file names. Globs include symbols for arbitrary single characters (\?), single characters from a specified range (\[a-z\]), arbitrary substrings (\*), and substrings from a specified finite set (\{foo,ba\{r,z\}\}). Globs are significantly less powerful than regular expressions.

### 2.5 Regular Expression Trees

Regular expressions are convenient notational shorthand for a more explicit representation of regular languages called *regular expression trees*. A regular expression tree is formally defined as one of the following:

- A leaf node labeled $\emptyset$.
- A leaf node labeled with a string in $\Sigma^*$.
- A node labeled $+$ with two children, each of which is the root of a regular expression tree.
- A node labeled $\cdot$ with two children, each of which is the root of a regular expression tree.
- A node labeled $*$ with one child, which is the root of a regular expression tree.

These cases mirror the definition of regular language exactly. A leaf labeled $\emptyset$ represents the empty language; a leaf labeled with a string represents the language containing only that string; a node labeled $+$ represents the union of the languages represented by its two children; a node labeled $\cdot$ represents the concatenation of the languages represented by its two children; and a node labeled $*$ represents the Kleene closure of the languages represented by its child.

A regular expression tree for $0^*1(0^*1 + 01^*)10^*$

A *subexpression* of a regular expression $R$ is another regular expression $S$ whose regular expression tree is a subtree of some regular expression tree for $R$. A *proper subexpression* of $R$ is any subexpression except $R$ itself. Every subexpression of $R$ is also a substring of $R$, but not every substring is a subexpression. For example, the substring $10^*1$ is a proper subexpression of $0^*1(10^*1 + 01^*)10^*$. However, the substrings $0^*1$ and $0^*1 + 01^*$ are *not* subexpressions of $0^*1(10^*1 + 01^*)10^*$, even though they are well-formed regular expressions.
2.6 Proofs about Regular Expressions

The standard strategy for proving properties of regular expressions, just as for any other recursively defined structure, is to argue inductively on the structure of the expression, as if it were expanded into a regular expression tree, rather than considering the regular expression as a raw string.

Induction proofs about regular expressions follow a standard boilerplate that mirrors the recursive definition of regular languages. Suppose we want to prove that every regular expression is perfectly cromulent, whatever that means. The white boxes hide additional proof details that, among other things, depend on the precise definition of “perfectly cromulent”. The boilerplate structure is longer than the boilerplate for string induction proofs, but don’t be fooled into thinking it’s harder.

**Proof:** Let $R$ be an arbitrary regular expression. Assume that every proper subexpression of $R$ is perfectly cromulent.

There are five cases to consider.

- Suppose $R = \epsilon$.

Therefore, $R$ is perfectly cromulent.

- Suppose $R$ is a single string.

Therefore, $R$ is perfectly cromulent.

- Suppose $R = S + T$ for some regular expressions $S$ and $T$.
  
  The induction hypothesis implies that $S$ and $T$ are perfectly cromulent.

Therefore, $R$ is perfectly cromulent.

- Suppose $R = S \cdot T$ for some regular expressions $S$ and $T$.
  
  The induction hypothesis implies that $S$ and $T$ are perfectly cromulent.

Therefore, $R$ is perfectly cromulent.

- Suppose $R = S^*$ for some regular expression $S$.
  
  The induction hypothesis implies that $S$ is perfectly cromulent.

Therefore, $w$ is perfectly cromulent.

In both cases, we conclude that $w$ is perfectly cromulent. □

Here is an example of this induction boilerplate in action. Again, this proof is longer than a typical induction proof about strings or integers, but each individual case is still short.

**Lemma 2.4.** Every regular expression that does not use the symbol $\emptyset$ represents a non-empty language.
Proof: Let $R$ be an arbitrary regular expression that does not use the symbol $\emptyset$. Assume that every proper subexpression of $R$ represents a non-empty language. There are five cases to consider.

- If $R = \emptyset$, we have a contradiction; we can ignore this case.
- If $R$ is a single string $w$, then $L(R) = L(w) = \{w\}$.
- Suppose $R = S + T$ for some regular expressions $S$ and $T$. $S$ does not use the symbol $\emptyset$, so the inductive hypothesis implies that $L(S)$ is non-empty. Choose an arbitrary string $x \in S$. Then $L(R) = L(S + T) = L(S) \cup L(T)$ also contains the string $x$.
- Suppose $R = S \cdot T$ for some regular expressions $S$ and $T$. Neither $S$ nor $T$ includes the symbol $\emptyset$, so the inductive hypothesis implies that both $L(S)$ and $L(T)$ are non-empty. Choose arbitrary strings $x \in S$ and $y \in T$. Then $L(R) = L(R \cdot T) = L(S) \cdot L(T)$ contains the string $xy$.
- Suppose $R = S^*$ for some regular expression $S$. $S$ does not include the symbol $\emptyset$, so the inductive hypothesis implies that $L(S)$ is non-empty. Choose an arbitrary string $x \in S$. Then $L(R) = L(S^*) = L(S)^*$ also contains the string $x$ (as well as $\epsilon, x^3, x^{10^{100}}$, and so on).

In every case, $R$ represents a non-empty language. \hfill $\square$

The same strategy applies to inductive arguments about properties of regular languages. Rather than reasoning directly about an arbitrary regular language as a (possibly infinite) set of strings, it is usually more fruitful to argue inductively about the structure of some regular expression that represents that language.

Lemma 2.5. Every non-empty regular language is represented by a regular expression that does not use the symbol $\emptyset$.

Proof: Let $R$ be an arbitrary regular expression; we need to prove that either $L(R) = \emptyset$ or $L(R) = L(R')$ for some $\emptyset$-free regular expression $R'$. For every proper subexpression $S$ of $R$ (represented by a proper subtree of $R$'s regular expression tree), assume that either $L(S) = \emptyset$ or $L(S) = L(S')$ for some $\emptyset$-free regular expression $S'$. There are five cases to consider.

- If $R = \emptyset$, then $L(R) = \emptyset$.
- If $R$ is a single string $w$, then $R$ is already $\emptyset$-free.
- Suppose $R = S + T$ for some regular expressions $S$ and $T$. There are four subcases to consider:
  - If $L(S) = L(T) = \emptyset$, then $L(R) = L(S) \cup L(T) = \emptyset$.
  - Suppose $L(S) \neq \emptyset$ and $L(T) = \emptyset$. The inductive hypothesis implies that there is a $\emptyset$-free regular expression $S'$ such that $L(S') = L(S) = L(S) \cup L(T) = L(R)$.
  - Suppose $L(S) = \emptyset$ and $L(T) \neq \emptyset$. The inductive hypothesis implies that there is a $\emptyset$-free regular expression $T'$ such that $L(T') = L(T) = L(S) \cup L(T) = L(R)$.
  - Finally, suppose $L(S) \neq \emptyset$ and $L(T) \neq \emptyset$. The inductive hypothesis implies that there are $\emptyset$-free regular expressions $S'$ and $T'$ such that $L(S') = L(S)$ and $L(T') = L(T)$. The regular expression $S' + T'$ is $\emptyset$-free and $L(S' + T') = L(S') \cup L(T') = L(S) \cup L(T) = L(S + T) = L(R)$.
• Suppose $R = S \cdot T$ for some regular expressions $S$ and $T$. There are two subcases to consider.
  
  – If either $L(S) = \emptyset$ or $L(T) = \emptyset$ then $L(R) = L(S) \cdot L(T) = \emptyset$.
  
  – Otherwise, the inductive hypothesis implies that there are $\emptyset$-free regular expressions $S'$ and $T'$ such that $L(S') = L(S)$ and $L(T') = L(T)$. The regular expression $S' \cdot T'$ is $\emptyset$-free and equivalent to $R$.

• Suppose $R = S^*$ for some regular expression $S$. There are two subcases to consider.
  
  – If $L(S) = \emptyset$, then $L(R) = \emptyset^* = \{\varepsilon\}$, so $R$ is represented by the $\emptyset$-free regular expression $\varepsilon$.
  
  – Otherwise, the inductive hypothesis implies that there is a $\emptyset$-free regular expression $S'$ such that $L(S') = L(S)$. The regular expression $(S')^*$ is $\emptyset$-free and equivalent to $R$.

In all cases, either $L(R) = \emptyset$ or $L(R) = L(R')$ for some $\emptyset$-free regular expression $R'$.  

Similarly, most algorithms that accept regular expressions as input actually require regular expression trees, rather than regular expressions as raw strings. Fortunately, it is possible to parse any regular expression of length $n$ into an equivalent regular expression tree in $O(n)$ time. (The details of this algorithm are beyond the scope of this chapter.) Thus, when we see an algorithmic problem that starts “Given a regular expression...”, we can assume without loss of generality that we’re actually given a regular expression tree.

2.7 Not Every Language is Regular

You may be tempted to conjecture that all languages are regular, but in fact, the following cardinality argument almost all languages are not regular. To make the argument concrete, let’s consider languages over the single-symbol alphabet $\{ \diamond \}$.

• Every regular expression over the one-symbol alphabet $\{ \diamond \}$ is itself a string over the seven-symbol alphabet $\{ \diamond, +, (, ) , *, \varepsilon, \emptyset \}$. By interpreting these symbols as the digits 1 through 7, we can interpret any string over this larger alphabet as the base-8 representation of some unique integer. Thus, the set of all regular expressions over $\{ \diamond \}$ is at most as large as the set of integers, and is therefore countably infinite. It follows that the set of all regular languages over $\{ \diamond \}$ is also countably infinite.

• On the other hand, for any real number $0 \leq \alpha < 1$, we can define a corresponding language

\[ L_\alpha = \{ \diamond^n \mid \alpha 2^n \text{ mod } 1 \geq 1/2 \}. \]

In other words, $L_\alpha$ contains the string $\diamond^n$ if and only if the $(n+1)$th bit in the binary representation of $\alpha$ is equal to 1. For any distinct real numbers $\alpha \neq \beta$, the binary representations of $\alpha$ and $\beta$ must differ in some bit, so $L_\alpha \neq L_\beta$. We conclude that the set of all languages over $\{ \diamond \}$ is at least as large as the set of real numbers between 0 and 1, and is therefore uncountably infinite.

We will see several explicit examples of non-regular languages in later lectures. In particular, the set of all regular expressions over the alphabet $\{0, 1\}$ is a non-regular language over the alphabet $\{0, 1, +, (, ) , *, \varepsilon, \emptyset\}$. 

8
Exercises

1. (a) Prove that $\{\epsilon\} \cdot L = L \cdot \{\epsilon\} = L$, for any language $L$.
(b) Prove that $\emptyset \cdot L = L \cdot \emptyset = \emptyset$, for any language $L$.
(c) Prove that $(A \cdot B) \cdot C = A \cdot (B \cdot C)$, for all languages $A$, $B$, and $C$.
(d) Prove that $|A \cdot B| = |A| \cdot |B|$, for all languages $A$ and $B$. (The second $\cdot$ is multiplication!)
(e) Prove that $L^*$ is finite if and only if $L = \emptyset$ or $L = \{\epsilon\}$.
(f) Prove that $AB = BC$ implies $A^*B = BC^* = A^*BC^*$, for all languages $A$, $B$, and $C$.

2. Recall that the reversal $w^R$ of a string $w$ is defined recursively as follows:

$$w^R := \begin{cases} 
\epsilon & \text{if } w = \epsilon \\
 x^R \cdot a & \text{if } w = a \cdot x 
\end{cases}$$

The reversal $L^R$ of any language $L$ is the set of reversals of all strings in $L$:

$$L^R := \{w^R \mid w \in L\}.$$ 

(a) Prove that $(AB)^R = B^RA^R$ for all languages $A$ and $B$.
(b) Prove that $(L^R)^R = L$ for every language $L$.
(c) Prove that $(L^*)_R = (L^R)^*$ for every language $L$.

3. Prove that each of the following regular expressions is equivalent to $(0 + 1)^*$.

(a) $\epsilon + 0(0 + 1)^* + 1(1 + 0)^*$
(b) $0^* + 0^*1(0 + 1)^*$
(c) $((\epsilon + 0)(\epsilon + 1))^*$
(d) $0^*(10^*)^*$
(e) $(1^*0)^*(0^*1)^*$

4. For each of the following languages in $\{0, 1\}^*$, describe an equivalent regular expression. There are infinitely many correct answers for each language. (This problem will become significantly simpler after we’ve seen finite-state machines.)

(a) Strings that end with the suffix $0^9 = 000000000$.
(b) All strings except $010$.
(c) Strings that contain the substring $010$.
(d) Strings that contain the subsequence $010$.
(e) Strings that do not contain the substring $010$.
(f) Strings that do not contain the subsequence $010$.
(g) Strings that contain an even number of occurrences of the substring $010$.
(h) Strings that contain an even number of occurrences of the substring $000$. 

\*
(i) Strings in which every occurrence of the substring 00 appears before every occurrence of the substring 11.

(j) Strings \( w \) such that in every prefix of \( w \), the number of 0s and the number of 1s differ by at most 1.

*(k) Strings \( w \) such that in every prefix of \( w \), the number of 0s and the number of 1s differ by at most 2.

*(l) Strings in which the number of 0s and the number of 1s differ by a multiple of 3.

*(m) Strings that contain an even number of 1s and an odd number of 0s.

* (n) Strings that represent a number divisible by 5 in binary.

5. Prove that for every regular language \( L \), the language \( L^R \) is also regular. [Hint: How do you reverse a regular expression?]

6. (a) Describe and analyze an efficient algorithm to determine, given a regular expression \( R \), whether \( L(R) \) is empty.

(b) Describe and analyze an efficient algorithm to determine, given a regular expression \( R \), whether \( L(R) \) is infinite.

In each problem, assume you are given \( R \) as a regular expression tree, not just a raw string.
