Based in part on slides by Mattox Beckman, as updated by Vikram Adve and Gul Agha

BNF Grammars

- Start with a set of characters, a,b,c,...
 - We call these terminals
- Add a set of different characters, X,Y,Z,
 - We call these nonterminals
- One special nonterminal S called start symbol

BNF Grammars

BNF rules (aka productions) have form

$$X := y$$

where X is any nonterminal and y is a string of terminals and nonterminals

 BNF grammar is a set of BNF rules such that every nonterminal appears on the left of some rule

Sample Grammar

Terminals: 0 1 + () Nonterminals: <Sum> Start symbol = <Sum> <Sum> ::= 0 <Sum >::= 1 <Sum> ::= <Sum> + <Sum> <Sum> ::= (<Sum>) Can be abbreviated as <Sum> ::= 0 | 1 | <Sum> + <Sum> | ()

Given rules

$$X::= yZw$$
 and $Z::= v$
we may replace Z by v to say
 $X => yZw => yvw$

- Sequence of such replacements called derivation
- Derivation called *right-most* if always replace the right-most non-terminal

 The meaning of a BNF grammar is the set of all strings consisting only of terminals that can be derived from the Start symbol

Start with the start symbol:

Pick a non-terminal

Pick a rule and substitute:

Pick a non-terminal:

Pick a rule and substitute:

Pick a non-terminal:

Pick a rule and substitute:

BNF Derivations

Pick a non-terminal:

Pick a rule and substitute:

BNF Derivations

Pick a non-terminal:

BNF Derivations

Pick a rule and substitute:

Pick a non-terminal:

BNF Derivations

Pick a rule and substitute

BNF Derivations

 \bullet (0 + 1) + 0 is generated by grammar

Regular Grammars

- Subclass of BNF
- Only rules of form <nonterminal>::=<terminal><nonterminal>::=<terminal> or <nonterminal>::=ε
- Defines same class of languages as regular expressions
- Important for writing lexers (programs that convert strings of characters into strings of tokens)

Example

Regular grammar:

```
<Balanced> ::= ε

<Balanced> ::= 0<OneAndMore>

<Balanced> ::= 1<ZeroAndMore>

<OneAndMore> ::= 1<Balanced>

<ZeroAndMore> ::= 0<Balanced>
```

 Generates even length strings where every initial substring of even length has same number of 0's as 1's

Extended BNF Grammars

- Alternatives: allow rules of from X:=y/z
 - Abbreviates X::= y, X::= z
- Options: X := y[v]z
 - Abbreviates X::= yvz, X::= yz
- Repetition: $X := y\{v\}*z$
 - Can be eliminated by adding new nonterminal V and rules X::= yz, X::= yVz, V::= v, V::= w

Parse Trees

- Graphical representation of derivation
- Each node labeled with either non-terminal or terminal
- If node is labeled with a terminal, then it is a leaf (no sub-trees)
- If node is labeled with a non-terminal, then it has one branch for each character in the right-hand side of rule used to substitute for it

Example

Consider grammar:

Problem: Build parse tree for 1 * 1 + 0 as an <exp>

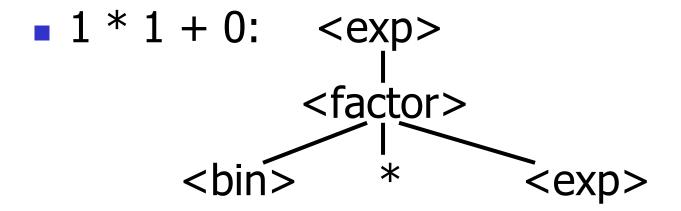

■ 1 * 1 + 0: <exp>

<exp> is the start symbol for this parse
 tree

Exa

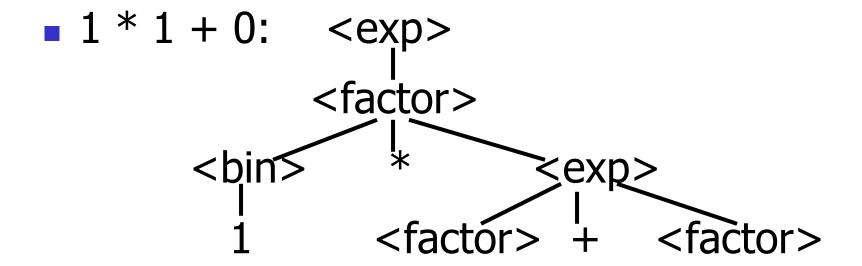

Example cont.

Use rule: <exp> ::= <factor>

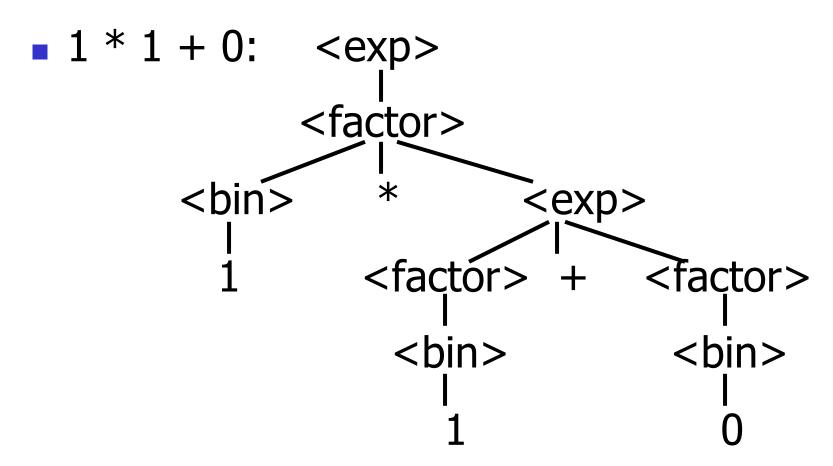

Use rule: <factor> ::= <bin> * <exp>

Example cont.

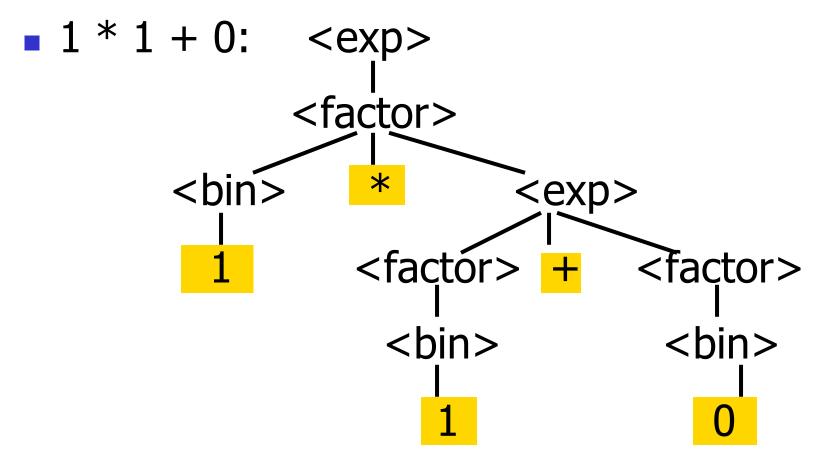

```
Use rules: <bin> ::= 1 and <br/> <exp> ::= <factor> +
```

Use rule: <factor> ::= <bin>

Use rules: <bin> ::= 1 | 0

Fringe of tree is string generated by grammar

Parse Tree Data Structures

- Parse trees may be represented by OCaml datatypes
- One datatype for each nonterminal
- One constructor for each rule
- Defined as mutually recursive collection of datatype declarations

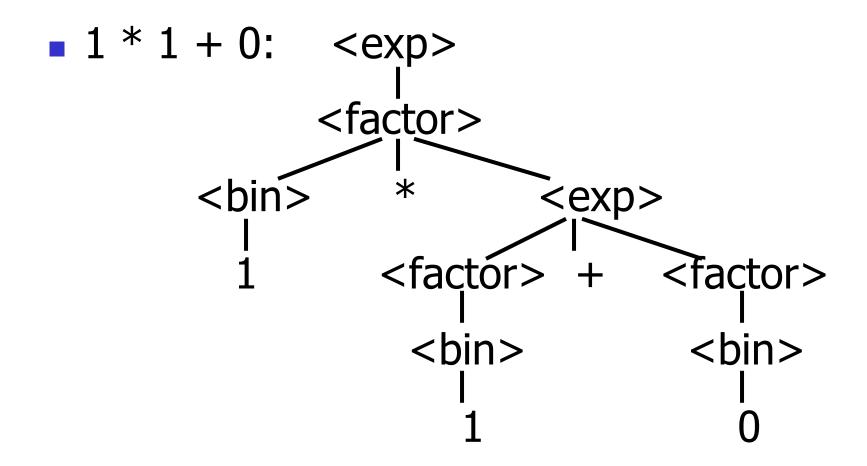

Example

Recall grammar:

```
<exp> ::= <factor> | <factor> + <factor>
                         <factor> ::= <bin> | <bin> * <exp>
                         <br/>

type exp = Factor2Exp of factor
                                                                                                                                 | Plus of factor * factor
                          and factor = Bin2Factor of bin
                                                                                                                                                              | Mult of bin * exp
                          and bin = Zero | One
```

Example cont.

Example cont.

Can be represented as

```
Factor2Exp
(Mult(One,
Plus(Bin2Factor One,
Bin2Factor Zero)))
```

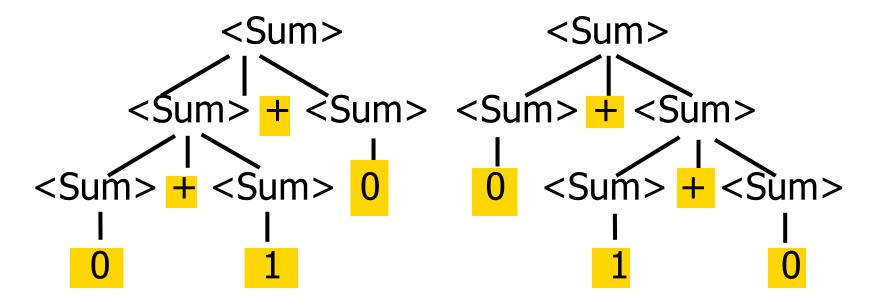

Ambiguous Grammars and Languages

- A BNF grammar is ambiguous if its language contains strings for which there is more than one parse tree
- If all BNF's for a language are ambiguous then the language is inherently ambiguous

Example: Ambiguous Grammar

$$0 + 1 + 0$$

What is the result for:

$$3 + 4 * 5 + 6$$

What is the result for:

$$3 + 4 * 5 + 6$$

Possible answers:

- 41 = ((3 + 4) * 5) + 6
- 47 = 3 + (4 * (5 + 6))
- 29 = (3 + (4 * 5)) + 6 = 3 + ((4 * 5) + 6)
- 77 = (3 + 4) * (5 + 6)

What is the value of:

$$7 - 5 - 2$$

What is the value of:

$$7 - 5 - 2$$

- Possible answers:
 - In Pascal, C++, SML assoc. left

$$7-5-2=(7-5)-2=0$$

In APL, associate to right

$$7-5-2=7-(5-2)=4$$

Two Major Sources of Ambiguity

- Lack of determination of operator precedence
- Lack of determination of operator assoicativity

Not the only sources of ambiguity

Disambiguating a Grammar

 Given ambiguous grammar G, with start symbol S, find a grammar G' with same start symbol, such that

language of G = language of G'

- Not always possible
- No algorithm in general

Disambiguating a Grammar

- Idea: Each non-terminal represents all strings having some property
- Identify these properties (often in terms of things that can't happen)
- Use these properties to inductively guarantee every string in language has a unique parse

- Identify the rules and a smallest use that display ambiguity
- Decide which parse to keep; why should others be thrown out?
- What syntactic restrictions on subexpressions are needed to throw out the bad (while keeping the good)?
- Add a new non-terminal and rules to describe this set of restricted subexpressions (called stratifying, or refactoring)
- Replace old rules to use new non-terminals
- Rinse and repeat

Ambiguous grammar:

String with more then one parse:

$$0 + 1 + 0$$
 $1 * 1 + 1$

Sourceof ambiuity: associativity and precedence

Two Major Sources of Ambiguity

- Lack of determination of operator precedence
- Lack of determination of operator assoicativity

Not the only sources of ambiguity

How to Enforce Associativity

 Have at most one recursive call per production

 When two or more recursive calls would be natural leave right-most one for right assoicativity, left-most one for left assoiciativity

Becomes

- <Sum> ::= <Num> | <Num> + <Sum>
- Num> ::= 0 | 1 | (<Sum>)

 Operators of highest precedence evaluated first (bind more tightly).

 Precedence for infix binary operators given in following table

Needs to be reflected in grammar

Precedence Table - Sample

	Fortan	Pascal	C/C++	Ada	SML
highest	**	*, /, div, mod	++,	**	div, mod, / , *
	*,/	+, -	*,/,	*, /, mod	+,-,
	+,-		+, -	+, -	::

10/4/07

First Example Again

- In any above language, 3 + 4 * 5 + 6= 29
- In APL, all infix operators have same precedence
 - Thus we still don't know what the value is (handled by associativity)
- How do we handle precedence in grammar?

Predence in Grammar

- Higher precedence translates to longer derivation chain
- Example:

Becomes

- < grammar>.ml defines one parsing function per entry point
- Parsing function takes a lexing function (lexer buffer to token) and a lexer buffer as arguments
- Returns semantic attribute of corresponding entry point

Ocamlyacc Input

File format:

```
%{
   <header>
%}
   <declarations>
%%
   <rules>
%%
   <trailer>
```

Ocamlyacc < header>

- Contains arbitrary Ocaml code
- Typically used to give types and functions needed for the semantic actions of rules and to give specialized error recovery
- May be omitted
- <footer> similar. Possibly used to call parser

Ocamlyacc <declarations>

- %token symbol ... symbol
- Declare given symbols as tokens
- %token <type> symbol ... symbol
- Declare given symbols as token constructors, taking an argument of type <type>
- %start symbol ... symbol
- Declare given symbols as entry points; functions of same names in < grammar>.ml

Ocamlyacc < declarations>

- %type <type> symbol ... symbol Specify type of attributes for given symbols. Mandatory for start symbols
- %left symbol ... symbol
- %right symbol ... symbol
- %nonassoc symbol ... symbol
 Associate precedence and associativity to given symbols. Same line, same precedence; earlier line, lower precedence (broadest scope)

Ocamlyacc < rules>

```
    nonterminal:
        symbol ... symbol { semantic_action }
        ...
        | symbol ... symbol { semantic_action }
        ;
        ;
        / symbol ... symbol { semantic_action }
        ;
        / symbol ... symbol { semantic_action }
        / symbol ... symbol ... symbol { semantic_action }
        / symbol ... s
```

- Semantic actions are arbitrary Ocamle expressions
- Must be of same type as declared (or inferred) for nonterminal
- Access semantic attributes (values) of symbols by position: \$1 for first symbol, \$2 to second ...

Example - Base types

```
(* File: expr.ml *)
type expr =
  Term_as_Expr of term
 | Plus Expr of (term * expr)
 | Minus Expr of (term * expr)
and term =
   Factor as Term of factor
  Mult_Term of (factor * term)
  Div Term of (factor * term)
and factor =
  Id as Factor of string
  Parenthesized Expr as Factor of expr
```

Example - Lexer (exprlex.mll)

```
{ (*open Exprparse*) }
let numeric = \lceil '0' - '9' \rceil
let letter = ['a' - 'z' 'A' - 'Z']
rule token = parse
 | "+" {Plus token}
 | "-" {Minus_token}
 | "*" {Times_token}
 | "/" {Divide token}
  "(" {Left_parenthesis}
  ")" {Right parenthesis}
  | letter (letter|numeric|"_")* as id {Id_token id}
  [' ' '\t' '\n'] {token lexbuf}
  eof {EOL}
```

Example - Parser (exprparse.mly)

```
%{ open Expr
%}
%token <string> Id_token
%token Left_parenthesis Right_parenthesis
%token Times token Divide token
%token Plus token Minus token
%token EOL
%start main
%type <expr> main
%%
```

Example - Parser (exprparse.mly)

```
term
     term_as_Expr $1 }
| term Plus_token expr
     { Plus_Expr ($1, $3) }
| term Minus_token expr
     { Minus_Expr ($1, $3) }
```

Example - Parser (exprparse.mly)

{ Div Term (\$1, \$3) }

Example - Parser (exprparse.mly)

```
factor:
  Id token
    { Id_as_Factor $1 }
| Left_parenthesis expr Right_parenthesis
    {Parenthesized_Expr_as_Factor $2 }
main:
expr EOL
     { $1 }
```

Example - Using Parser

```
# #use "expr.ml";;
# #use "exprparse.ml";;
# #use "exprlex.ml";;
# let test s =
 let lexbuf = Lexing.from_string (s^"\n") in
     main token lexbuf;;
```

Example - Using Parser

```
# test "a + b";;
-: expr =
Plus_Expr
(Factor_as_Term (Id_as_Factor "a"),
   Term_as_Expr (Factor_as_Term
   (Id_as_Factor "b")))
```

LR Parsing

- Read tokens left to right (L)
- Create a rightmost derivation (R)
- How is this possible?
- Start at the bottom (left) and work your way up
- Last step has only one non-terminal to be replaced so is right-most
- Working backwards, replace mixed strings by non-terminals
- Always proceed so that there are no nonterminals to the right of the string to be replaced

                                 shift
```

(0 + 1) + 0

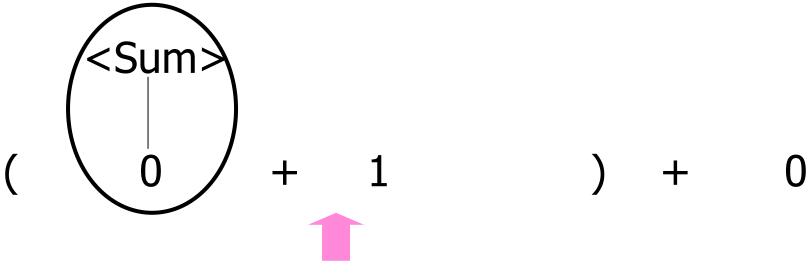

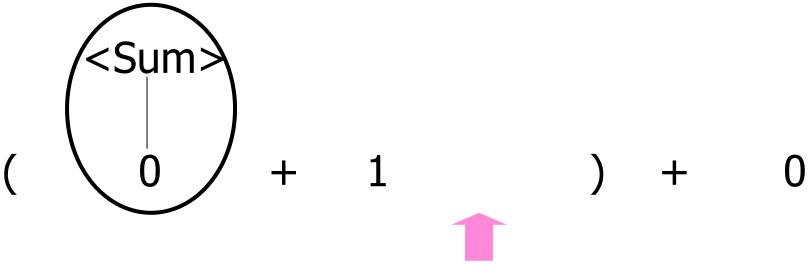

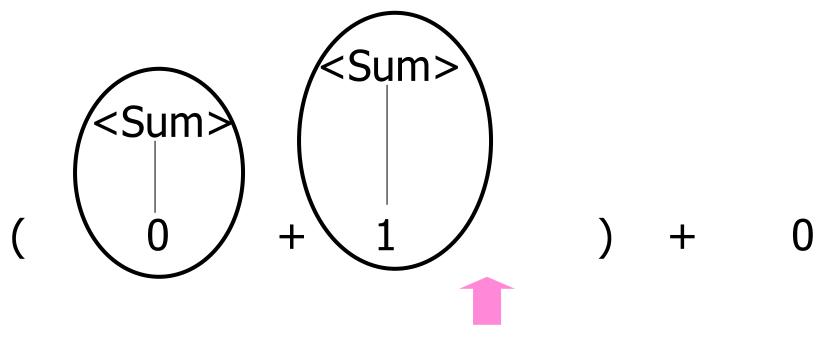

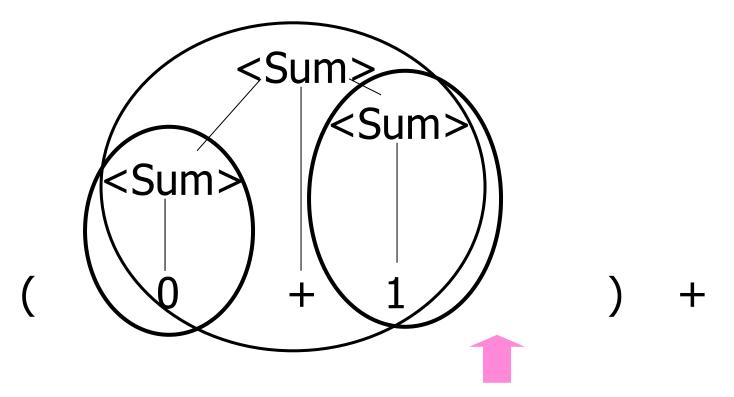

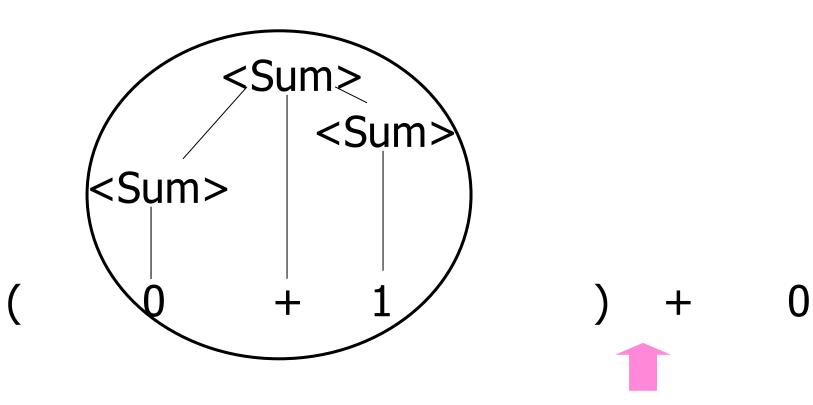

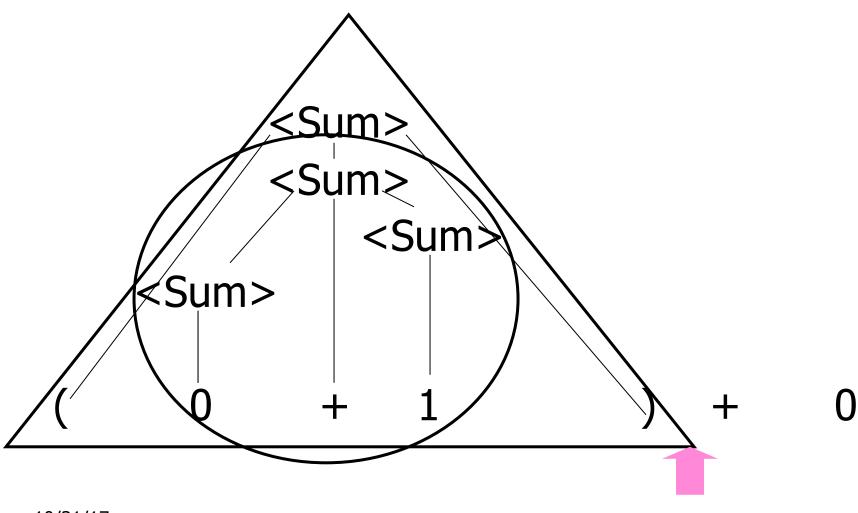

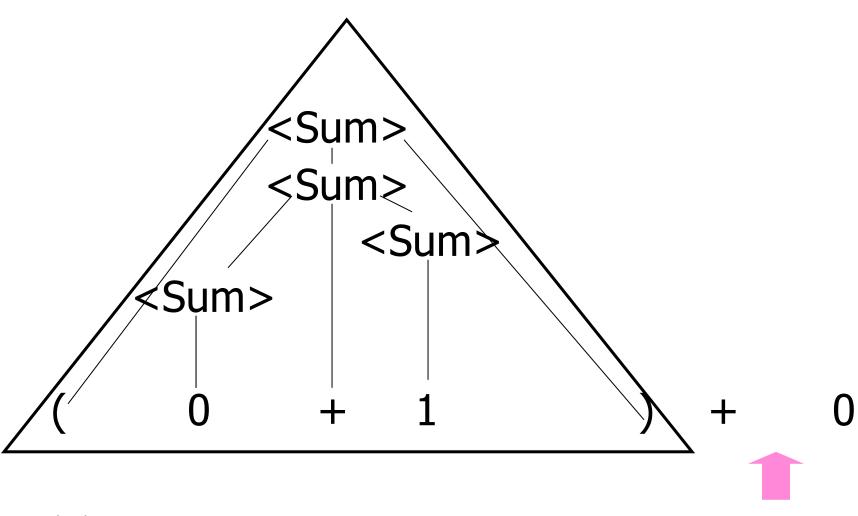

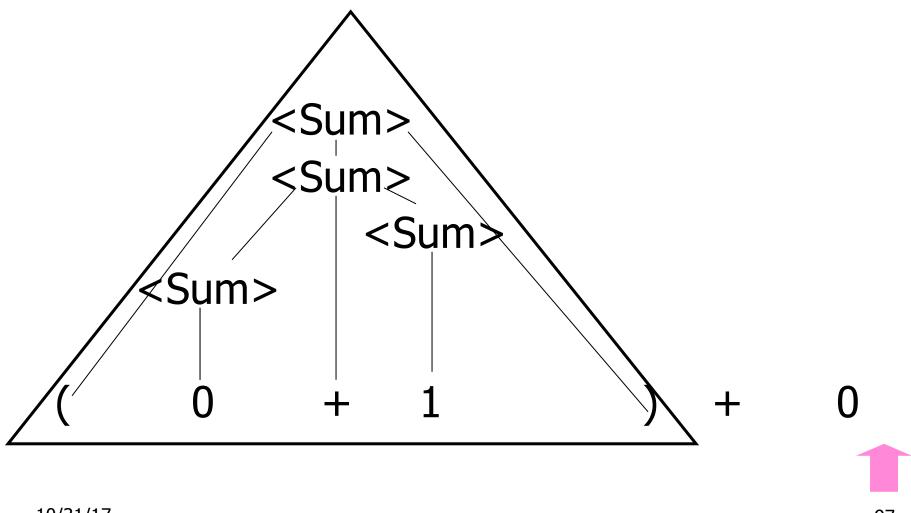

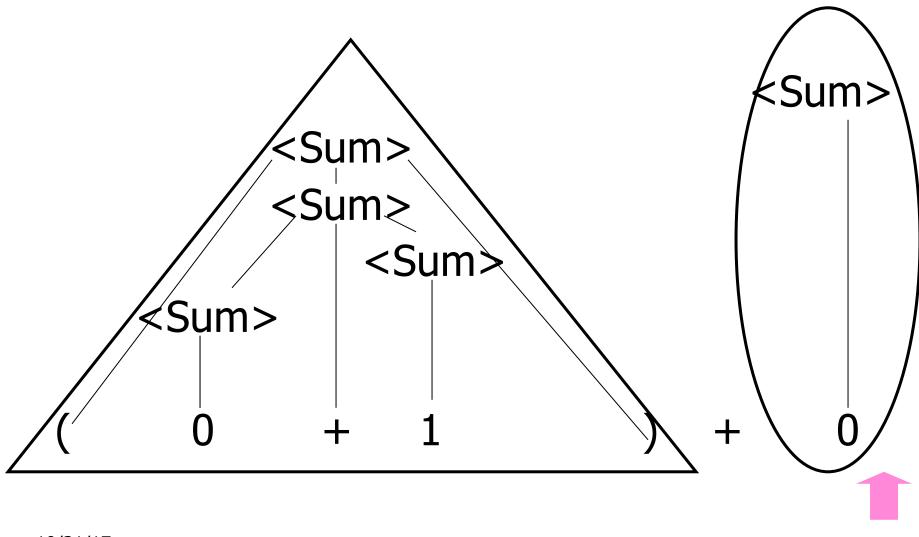

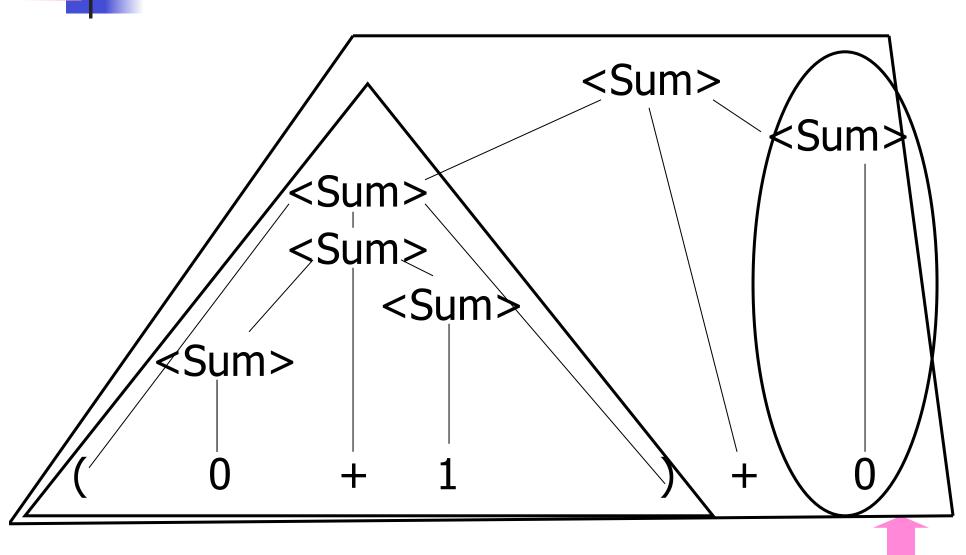

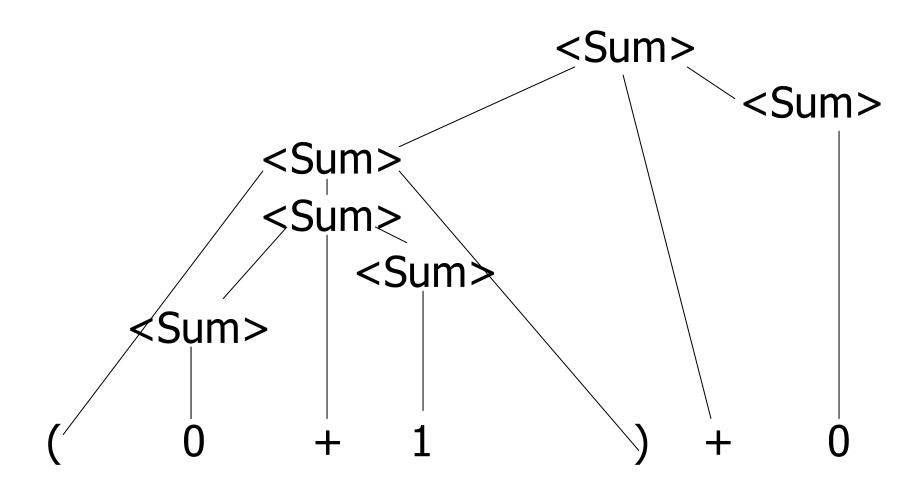

LR Parsing Tables

- Build a pair of tables, Action and Goto, from the grammar
 - This is the hardest part, we omit here
 - Rows labeled by states
 - For Action, columns labeled by terminals and "end-of-tokens" marker
 - (more generally strings of terminals of fixed length)
 - For Goto, columns labeled by nonterminals

Action and Goto Tables

- Given a state and the next input, Action table says either
 - shift and go to state n, or
 - reduce by production k (explained in a bit)
 - accept or error
- Given a state and a non-terminal, Goto table says
 - go to state m

- Based on push-down automata
- Uses states and transitions (as recorded in Action and Goto tables)
- Uses a stack containing states, terminals and non-terminals

- O. Insure token stream ends in special "endof-tokens" symbol
- 1. Start in state 1 with an empty stack
- 2. Push **state**(1) onto stack
- →3. Look at next *i* tokens from token stream (toks) (don't remove yet)
 - 4. If top symbol on stack is **state**(*n*), look up action in Action table at (*n*, *toks*)

5. If action = **shift** m,

- a) Remove the top token from token stream and push it onto the stack
- b) Push **state**(*m*) onto stack
- c) Go to step 3

- 6. If action = **reduce** *k* where production *k* is E ::= u
 - a) Remove 2 * length(u) symbols from stack (u and all the interleaved states)
 - b) If new top symbol on stack is **state**(*m*), look up new state *p* in Goto(*m*,E)
 - c) Push E onto the stack, then push **state**(*p*) onto the stack
 - d) Go to step 3

- 7. If action = accept
 - Stop parsing, return success
- 8. If action = error,
 - Stop parsing, return failure

Adding Synthesized Attributes

- Add to each reduce a rule for calculating the new synthesized attribute from the component attributes
- Add to each non-terminal pushed onto the stack, the attribute calculated for it
- When performing a reduce,
 - gather the recorded attributes from each nonterminal popped from stack
 - Compute new attribute for non-terminal pushed onto stack

Shift-Reduce Conflicts

- Problem: can't decide whether the action for a state and input character should be shift or reduce
- Caused by ambiguity in grammar
- Usually caused by lack of associativity or precedence information in grammar

4

Example: <Sum> = 0 | 1 | (<Sum>) | <Sum> + <Sum>

Problem: shift or reduce?

 You can shift-shift-reduce-reduce or reduce-shift-shift-reduce

- Shift first right associative
- Reduce first- left associative

Reduce - Reduce Conflicts

- Problem: can't decide between two different rules to reduce by
- Again caused by ambiguity in grammar
- Symptom: RHS of one production suffix of another
- Requires examining grammar and rewriting it
- Harder to solve than shift-reduce errors

- abc shift
- a bc shift
- ab c shift
- abc •
- Problem: reduce by B ::= bc then by
 - S ::= aB, or by A ::= abc then S ::A?
