

CS 421 Lecture 18 – More examples of higher-order functions

- ▶ Combinator programming – “parser combinators”
- ▶ Representing sets as higher-order functions
- ▶ Representing pairs as higher-order functions
- ▶ Building comparators using higher-order functions

Combinator-style programming

Can write complex programs by defining a library of higher-order functions and applying them to one another (and to first-order or built-in functions).

Advantage: easy of creating programs – programs are just expressions

Example: build a parser by writing “parser combinators”.

Parser combinators

Def A parser is a function from `token list -> (token list) option`.

Idea is to define functions that build parsers, rather than building parsers "by hand."

*type α option =
Some α | None*

E.g. Parser to recognize a single token:

token: char -> (token list -> (token list) option)

```
let token s = fun cl -> if cl=[] then None  
                    else if s=hd cl then Some (tl cl)  
                    else None;;
```

parser

```
let parsex = token 'x';;
```

```
parsex ['x'];; ⇒ Some []
```

```
parsex ['a'];; ⇒ None
```

Parser combinators

“Combinators” to combine parsers into larger parsers:

$++ : \text{parser} \rightarrow \text{parser} \rightarrow \text{parser}$

let (++) p q = fun cl -> match p cl with None -> None
| Some cl' -> q cl';;

let parsexy = token 'x' ++ token 'y'

parsexy ['x', 'y'] \Rightarrow Some []

parsexy ['x', 'z'] \Rightarrow None

$\text{double} (\text{token } 'x')$
 $['x', 'x'] \Rightarrow \text{Some } []$

let double p = fun cl -> match p cl with None -> None
| Some cl' -> p cl';;

or
 $= p ++ p$

Parser combinators

```
let (||) p q = fun cl -> match p cl with None -> q cl  
                        | Some cl' -> Some cl';;
```

```
let parsexyorz = parsexy || token 'z'
```

```
parsexyorz['x', 'y']
```

```
parsexyorz ['z']
```

Parser combinators

Put this together to define parser for grammar:

$A \rightarrow aB \mid b$

$B \rightarrow cB \mid A$

let rec parseA cl = ((token 'a' ++ parseB) || token 'b') cl

and parseB cl = ((token 'c' ++ parseB) || parseA) cl;;

parseA ['a';'c';'c';'a';'b']

Representing sets as higher-order functions

Def. A set is a function from values to bool.

type intset = int -> bool

E.g. {2} = fun x -> (x=2)

$\{n \mid n > 10\} = \text{fun } x \rightarrow x > 10$

{2,3} = fun x -> (x=2) or (x=3)

Set operations:

(* member: int -> intset -> bool *)

let member n s = s n ;;

(* emptyset: intset *)

let emptyset = fun x -> false ;;

Representing sets as higher-order functions

(* add: int -> intset -> intset *)

let add n s = fun x -> s x or x = n ;;

(* union: intset -> intset -> intset *)

let union s1 s2 = fun x -> s1 x or s2 x ;;

(* intersection: intset -> intset -> intset *)

let intersection s1 s2 = fun x -> s1 x and s2 x ;;

(* remove: int -> intset -> intset *)

let remove n s = fun x -> s x and x <> n

► Lecture 18

add 5 (add 3 emptyset)

fun x -> false

fun x -> (fun x -> false) x or x = 3

= (fun x -> x = 3)

fun x -> (fun x -> x = 3) x or x = 5

fun x -> x = 3 or x = 5

Representing sets as higher-order functions

(* complement: intset -> intset *)

let complement s = fun x → not (s x);;

(* intsAbove: int -> intset *)

let intsAbove n = fun x → x > n

Advantages: - Don't need recursion to define
 set op's
 - Infinite sets

Disadvantage: ←
 - Efficiency?

[Note: cannot list elements]

Consider:
add 3 (add 3
(add 3 (add 2 empty)))

Representing pairs as higher-order functions

Def A pair is a value p with a constructor $\text{pair}: \alpha \rightarrow \beta \rightarrow \text{pair}$, and functions $\text{fst}: \text{pair} \rightarrow \alpha$ and $\text{snd}: \text{pair} \rightarrow \beta$ such that $\text{fst}(\text{pair } a \ b) = a$ and $\text{snd}(\text{pair } a \ b) = b$.

let $\text{pair } a \ b = \text{fun } f \rightarrow f \ a \ b$

let $\text{fst } p = p \ (\text{fun } x \rightarrow \text{fun } y \rightarrow x)$

let $\text{snd } p = p \ (\text{fun } x \rightarrow \text{fun } y \rightarrow y)$

$p = \text{pair } 2 \ 3 = \text{fun } f \rightarrow f \ 2 \ 3$

$\text{fst } p = (\text{fun } f \rightarrow (f \ 2) \ 3) (\text{fun } x \rightarrow \text{fun } y \rightarrow x)$

$= ((\text{fun } x \rightarrow \text{fun } y \rightarrow x) \ 2) \ 3$

▶ Lecture 18

$= (\text{fun } y \rightarrow 2) \ 3 = 2$

Building comparators using higher-order functions

Def A *comparator* is a function of type $\alpha * \alpha \rightarrow \text{bool}$.

E.g. ($>$) is a comparator.

($=$) is a comparator.

Can build specific comparators, e.g.

```
fun lexorder2 (x,y) (x',y') = x < x' or (x = x' & y < y');;
```

```
lexorder2 ('a','b') ('a','c')
```

```
lexorder2 ('a','z') ('b','a')
```

```
lexorder2 ('b','b') ('a','c')
```

Building comparators using higher-order functions

But it's more fun to build them using higher-order functions:

or-comp : $(\alpha \rightarrow \alpha \rightarrow \text{bool}) \rightarrow (\alpha \rightarrow \alpha \rightarrow \text{bool}) \rightarrow (\alpha \rightarrow \alpha \rightarrow \text{bool})$

let or_comp comp1 comp2 = fun x y ->
 (comp1 x y) or (comp2 x y)

let lte = or_comp (<) (=)

let and_comp comp1 comp2 = fun x y ->
 (comp1 x y) & (comp2 x y)

Building comparators using higher-order functions

```
let lex_comp comp1 comp2 =  
  fun (x,y) (x',y') -> comp1 x x' or (x=x' & comp2 y y')
```

```
let lexorder2 = lex_comp (<) (<);;
```

Building comparators using higher-order functions

```
let lex_comp_list comp =  
  let rec aux lis1 lis2 = match (lis1, lis2) with  
    | [], _ -> true  
    | _, [] -> false  
    | ((x::x'), (y::y')) -> comp x y or (x=y & aux x' y')  
  in aux;;  
let alphalex = lex_comp_list (<);;
```

Compare pairs $(x, y) < (x', y')$ if x, x' are lists and $x < x'$ lex.

```
let pairless p1 p2 = alphalex (fst p1) (fst p2)
```

Preview of next lecture

Function objects in S-O languages =
an object with one operation, usually
called `apply`.

```
class PlusOne {  
    int apply (int i) { return i+1; }  
}
```

```
{  
    (new PlusOne().apply(3)) => 4  
}
```

```
class Plus {  
    int x;  
    public Plus (int x) { this.x = x; }  
    public int apply (int y) { return x+y; }  
}
```

```
Plus add3 = new Plus(3),  
{  
    add3.apply(4) => 7  
}
```
