Multicast Problem

Node with a piece of information to be communicated to everyone

Distributed Group of "Nodes" = Processes at Internet-based host
Other Communication Forms

- **Multicast** → message sent to a group of processes
- **Broadcast** → message sent to all processes (anywhere)
- **Unicast** → message sent from one sender process to one receiver process
Who Uses Multicast?

• A widely-used abstraction by almost all cloud systems
• Storage systems like Cassandra or a database
  – Replica servers for a key: Writes/reads to the key are multicast within the replica group
  – All servers: membership information (e.g., heartbeats) is multicast across all servers in cluster
• Online scoreboards (ESPN, French Open, FIFA World Cup)
  – Multicast to group of clients interested in the scores
• Stock Exchanges
  – Group is the set of broker computers
  – Groups of computers for High frequency Trading
• Air traffic control system
  – All controllers need to receive the same updates in the same order
Multicast Ordering

- Determines the meaning of “same order” of multicast delivery at different processes in the group
- Three popular flavors implemented by several multicast protocols
  1. FIFO ordering
  2. Causal ordering
  3. Total ordering
1. FIFO ordering

- Multicasts from each sender are received in the order they are sent, at all receivers
- Don’t worry about multicasts from different senders
- More formally
  - *If a correct process issues (sends) multicast(g,m) to group g and then multicast(g,m’), then every correct process that delivers m’ would already have delivered m.*
M1:1 and M1:2 should be received in that order at each receiver.

Order of delivery of M3:1 and M1:2 could be different at different receivers.
Multicasts whose send events are causally related, must be received in the same causality-obeying order at all receivers.

Formally:
- If $\text{multicast}(g,m) \rightarrow \text{multicast}(g,m')$ then any correct process that delivers $m'$ would already have delivered $m$.
- $(\rightarrow$ is Lamport’s happens-before)
M3:1 \rightarrow M3:2, and so should be received in that order at each receiver.

M1:1 \rightarrow M3:1, and so should be received in that order at each receiver.

M3:1 and M2:1 are concurrent and thus ok to be received in different orders at different receivers.
Causal vs. FIFO

- Causal Ordering $\Rightarrow$ FIFO Ordering
- Why?
  - If two multicasts $M$ and $M'$ are sent by the same process $P$, and $M$ was sent before $M'$, then $M \rightarrow M'$
  - Then a multicast protocol that implements causal ordering will obey FIFO ordering since $M \rightarrow M'$
- Reverse is not true! FIFO ordering does not imply causal ordering.
Why Causal at All?

- Group = set of your friends on a social network
- A friend sees your message m, and she posts a response (comment) m’ to it
  - If friends receive m’ before m, it wouldn’t make sense
  - But if two friends post messages m” and n” concurrently, then they can be seen in any order at receivers
- A variety of systems implement causal ordering: Social networks, bulletin boards, comments on websites, etc.
3. Total Ordering

- Also known as “Atomic Broadcast”
- Unlike FIFO and causal, this does not pay attention to order of multicast sending
- Ensures all receivers receive all multicasts in the same order
- Formally
  - *If a correct process P delivers message m before m’ (independent of the senders), then any other correct process P’ that delivers m’ would already have delivered m.*
The order of receipt of multicasts is the same at all processes.  
M1:1, then M2:1, then M3:1, then M3:2

May need to delay delivery of some messages
Hybrid Variants

• Since FIFO/Causal are orthogonal to Total, can have hybrid ordering protocols too
  – FIFO-total hybrid protocol satisfies both FIFO and total orders
  – Causal-total hybrid protocol satisfies both Causal and total orders
Implementation?

- That was *what* ordering is
- But *how* do we implement each of these orderings?
FIFO Multicast: Data Structures

• Each receiver maintains a per-sender sequence number (integers)
  – Processes $P_1$ through $P_N$
  – $P_i$ maintains a vector of sequence numbers $P_i[1...N]$ (initially all zeroes)
  – $P_i[j]$ is the latest sequence number $P_i$ has received from $P_j$
FIFO Multicast: Updating Rules

• Send multicast at process P_j:
  – Set P_j[j] = P_j[j] + 1
  – Include new P_j[j] in multicast message as its sequence number

• Receive multicast: If P_i receives a multicast from P_j with sequence number S in message
  – if (S == P_i[j] + 1) then
    • deliver message to application
    • Set P_i[j] = P_i[j] + 1
  – else buffer this multicast until above condition is true
FIFO Ordering: Example

P1  [0,0,0,0]  →  Time

P2  [0,0,0,0]  →

P3  [0,0,0,0]  →

P4  [0,0,0,0]  →
**FIFO Ordering: Example**

- **P1**: [1,0,0,0], seq: 1
- **P2**: [0,0,0,0] → [1,0,0,0] Deliver!
- **P3**: [0,0,0,0]
- **P4**: [0,0,0,0] → [1,0,0,0] Deliver!
FIFO Ordering: Example

Deliver! P1, seq: 1

Buffer! P1, seq: 2

Deliver this! Deliver buffered <P1, seq:2>

Update [2,0,0,0]
FIFO Ordering: Example
FIFO Ordering: Example
FIFO Ordering: Example
Total Ordering

- Ensures all receivers receive all multicasts in the same order
- Formally
  - If a correct process $P$ delivers message $m$ before $m'$ (independent of the senders), then any other correct process $P'$ that delivers $m'$ would already have delivered $m$. 
Sequencer-based Approach

• Special process elected as leader or sequencer
• Send multicast at process $P_i$:
  – Send multicast message $M$ to group and sequencer
• Sequencer:
  – Maintains a global sequence number $S$ (initially 0)
  – When it receives a multicast message $M$, it sets $S = S + 1$, and multicasts $<M, S>$
• Receive multicast at process $P_i$:
  – $P_i$ maintains a local received global sequence number $S_i$ (initially 0)
  – If $P_i$ receives a multicast $M$ from $P_j$, it buffers it until it both
    1. $P_i$ receives $<M, S(M)>$ from sequencer, and
    2. $S_i + 1 = S(M)$
  • Then deliver it message to application and set $S_i = S_i + 1$
Causal Ordering

• Multicasts whose send events are causally related, must be received in the same causality-obeying order at all receivers

• Formally
  – If $\text{multicast}(g,m) \rightarrow \text{multicast}(g,m')$ then any correct process that delivers $m'$ would already have delivered $m$.
  – ($\rightarrow$ is Lamport’s happens-before)
Causal Multicast: Datastructures

• Each receiver maintains a vector of per-sender sequence numbers (integers)
  – Similar to FIFO Multicast, but updating rules are different
  – Processes P1 through PN
  – Pi maintains a vector Pi[1…N] (initially all zeroes)
  – Pi[j] is the latest sequence number Pi has received from Pj
Causal Multicast: Updating Rules

• Send multicast at process $P_j$:
  – Set $P_j[j] = P_j[j] + 1$
  – Include new entire vector $P_j[1…N]$ in multicast message as its sequence number

• Receive multicast: If $P_i$ receives a multicast from $P_j$ with vector $M[1…N] (= P_j[1…N])$ in message, buffer it until both:
  1. This message is the next one $P_i$ is expecting from $P_j$, i.e.,
     • $M[j] = P_i[j] + 1$
  2. All multicasts, anywhere in the group, which happened-before M have been received at $P_i$, i.e.,
     • For all $k \neq j$: $M[k] \leq P_i[k]$
     • i.e., Receiver satisfies causality

  3. When above two conditions satisfied, deliver M to application and set $P_i[j] = M[j]$
Causal Ordering: Example
Causal Ordering: Example
Causal Ordering: Example
Causal Ordering: Example

P1: [0,0,0,0], Deliver!

P2: [0,0,0,0], [1,0,0,0], Deliver!

P3: [0,0,0,0], Missing 1 from P1, Buffer!

P4: [0,0,0,0], [1,0,0,0], [1,0,0,1], Deliver!

Receiver satisfies causality

P4
[0,0,0,0] [1,0,0,0] [1,0,0,1] [1,0,1,0]
Deliver P1’s multicast
Receiver satisfies causality for buffered multicasts
Deliver P2’s buffered multicast
Deliver P4’s buffered multicast

Causal Ordering: Example
Causal Ordering: Example

- **P1**: [0,0,0,0] [1,0,0,0] Deliver! Receiver satisfies causality
- **P2**: [0,0,0,0] [1,0,0,0] Deliver! [1,1,0,0] Deliver! Receiver satisfies causality
- **P3**: [0,0,0,0] [1,0,0,0] Deliver! Missing 1 from P1 Buffer!
- **P4**: [0,0,0,0] [1,0,0,0] [1,0,0,1] Deliver P1’s multicast

Deliver P2’s buffered multicast
Deliver P4’s buffered multicast
Receiver satisfies causality for buffered multicasts
Missing 1 from P1 Buffer!
Missing 1 from P1 Buffer!
Summary: Multicast Ordering

• Ordering of multicasts affects correctness of distributed systems using multicasts
• Three popular ways of implementing ordering
  – FIFO, Causal, Total
• And their implementations
• What about reliability of multicasts?
• What about failures?
• Reliable multicast loosely says that every process in the group receives all multicasts
  – Reliability is orthogonal to ordering
  – Can implement Reliable-FIFO, or Reliable-Causal, or Reliable-Total, or Reliable-Hybrid protocols
• What about process failures?
• Definition becomes vague
• Need all *correct* (i.e., non-faulty) processes to receive the same set of multicasts as all other correct processes
  – Faulty processes stop anyway, so we won’t worry about them
Let’s assume we have reliable unicast (e.g., TCP) available to us.

First-cut: Sender process (of each multicast M) sequentially sends a reliable unicast message to all group recipients.

First-cut protocol does not satisfy reliability:
- If sender fails, some correct processes might receive multicast M, while other correct processes might not receive M.
• Trick: Have receivers help the sender

1. Sender process (of each multicast M) sequentially sends a reliable unicast message to all group recipients

2. When a receiver receives multicast M, it also sequentially sends M to all the group’s processes
Analysis

- Not the most efficient multicast protocol, but reliable
- Proof is by contradiction
- Assume two correct processes $P_i$ and $P_j$ are so that $P_i$ received a multicast $M$ and $P_j$ did not receive that multicast $M$
  - Then $P_i$ would have sequentially sent the multicast $M$ to all group members, including $P_j$, and $P_j$ would have received $M$
  - A contradiction
  - Hence our initial assumption must be false
  - Hence protocol preserves reliability
Virtual Synchrony or View Synchrony

- Attempts to preserve multicast ordering and reliability in spite of failures
- Combines a membership protocol with a multicast protocol
- Systems that implemented it (like Isis Systems) have been used in NYSE, French Air Traffic Control System, Swiss Stock Exchange
Each process maintains a membership list
The membership list is called a *View*
An update to the membership list is called a *View Change*
  - Process join, leave, or failure
Virtual synchrony guarantees that all *view changes are delivered in the same order at all correct processes*
  - If a correct P1 process receives views, say \{P1\}, \{P1, P2, P3\}, \{P1, P2\}, \{P1, P2, P4\} then
  - Any other correct process receives the *same sequence* of view changes (after it joins the group)
    - P2 receives views \{P1, P2, P3\}, \{P1, P2\}, \{P1, P2, P4\}
Views may be delivered at different *physical* times at processes, but they are delivered in the same *order*
VSync Multicasts

- A multicast M is said to be “delivered in a view V at process $P_i$” if
  - $P_i$ receives view V, and then sometime before $P_i$ receives the next view it delivers multicast M

- Virtual synchrony ensures that
  1. The set of multicasts delivered in a given view is the same set at all correct processes that were in that view
     * What happens in a View, stays in that View
  2. The sender of the multicast message also belongs to that view
  3. If a process $P_i$ does not deliver a multicast M in view V while other processes in the view V delivered M in V, then $P_i$ will be forcibly removed from the next view delivered after V at the other processes
View\{P1,P2,P3,P4\}

View\{P1,P2,P3\}

View\{P1,P2,P3,P4\}

Satisfies virtual synchrony
Does not satisfy virtual synchrony
Does not satisfy virtual synchrony
Satisfies virtual synchrony
What about Multicast Ordering?

• Again, orthogonal to virtual synchrony
• The set of multicasts delivered in a view can be ordered either
  – FIFO
  – Or Causally
  – Or Totally
  – Or using a hybrid scheme
About that name

• Called “virtual synchrony” since in spite of running on an asynchronous network, it gives the appearance of a synchronous network underneath that obeys the same ordering at all processes
• So can this virtually synchronous system be used to implement consensus?
• No! VSync groups susceptible to partitioning
  – E.g., due to inaccurate failure detections
Partitioning in View synchronous systems
Summary

- Multicast an important building block for cloud computing systems
- Depending on application need, can implement
  - Ordering
  - Reliability
  - Virtual synchrony
Announcements

• Midterm next Tuesday

• Locations:
  – DCL 1320: if your last name starts with A-L
  – 1 THBH Room 134: if your last name starts with M-Z
    • Temple Hoyne Buell Hall, 611 Loredo Taft Drive Champaign, IL 61820

• Material through lecture 12 (Time and Ordering)
