

Chapter 5: Multiprocessors (Thread-Level Parallelism)– Part 2

Introduction

What is a parallel or multiprocessor system?

Why parallel architecture?

Performance potential

Flynn classification

Communication models

Architectures

Centralized sharedmemory

Distributed sharedmemory

Parallel programming

Synchronization

Memory consistency models

Memory Consistency Model - Motivation

Example shared-memory program

Initially all locations = 0

Processor 1

Data = 23

Flag = 1

Processor 2

while (Flag != 1) {;

... = Data

Execution (only shared-memory operations)

Processor 1

Write, Data, 23

Write, Flag, 1

Processor 2

Read, Flag, 1

Read, Data, ____

Memory Consistency Model: Definition

Memory consistency model

Order in which memory operations will appear to execute

⇒ What value can a read return?

Affects ease-of-programming and performance

The Uniprocessor Model

Program text defines total order = *program order*

Uniprocessor model

Memory operations appear to execute one-at-a-time in program order

⇒ Read returns value of last write

BUT uniprocessor hardware

Overlap, reorder operations

Model maintained as long as

maintain control and data dependences

⇒ Easy to use + high performance

Implicit Memory Model

Sequential consistency (SC) [Lamport]

Result of an execution appears as if

- All operations executed in some **sequential order** (i.e., atomically)
- Memory operations of each process in **program order**

Understanding Program Order – Example 1

Initially Flag1 = Flag2 = 0

P1

Flag1 = 1

if (Flag2 == 0)

critical section

P2

Flag2 = 1

if (Flag1 == 0)

critical section

Execution:

P1

(Operation, Location, Value)

Write, Flag1, 1

Read, Flag2, 0

P2

(Operation, Location, Value)

Write, Flag2, 1

Read, Flag1, ____

Understanding Program Order – Example 1

Can happen if

- Write buffers with read bypassing
- Overlap, reorder write followed by read in h/w or compiler
- Allocate Flag1 or Flag2 in registers

Understanding Program Order - Example 2

Initially A = Flag = 0

P1

A = 23;

Flag = 1;

P1

Write, A, 23

Write, Flag, 1

P2

while (Flag != 1) {;

... = A;

P2

Read, Flag, 0

Read, Flag, 1

Read, A, _____

Understanding Program Order - Example 2

Initially A = Flag = 0

P1

A = 23;

Flag = 1;

P1

Write, A, 23

Write, Flag, 1

P2

while (Flag != 1) {;}

... = A;

P2

Read, Flag, 0

Read, Flag, 1

Read, A, ~~0~~

Can happen if

Overlap or reorder writes or reads in hardware or compiler

Understanding Program Order: Summary

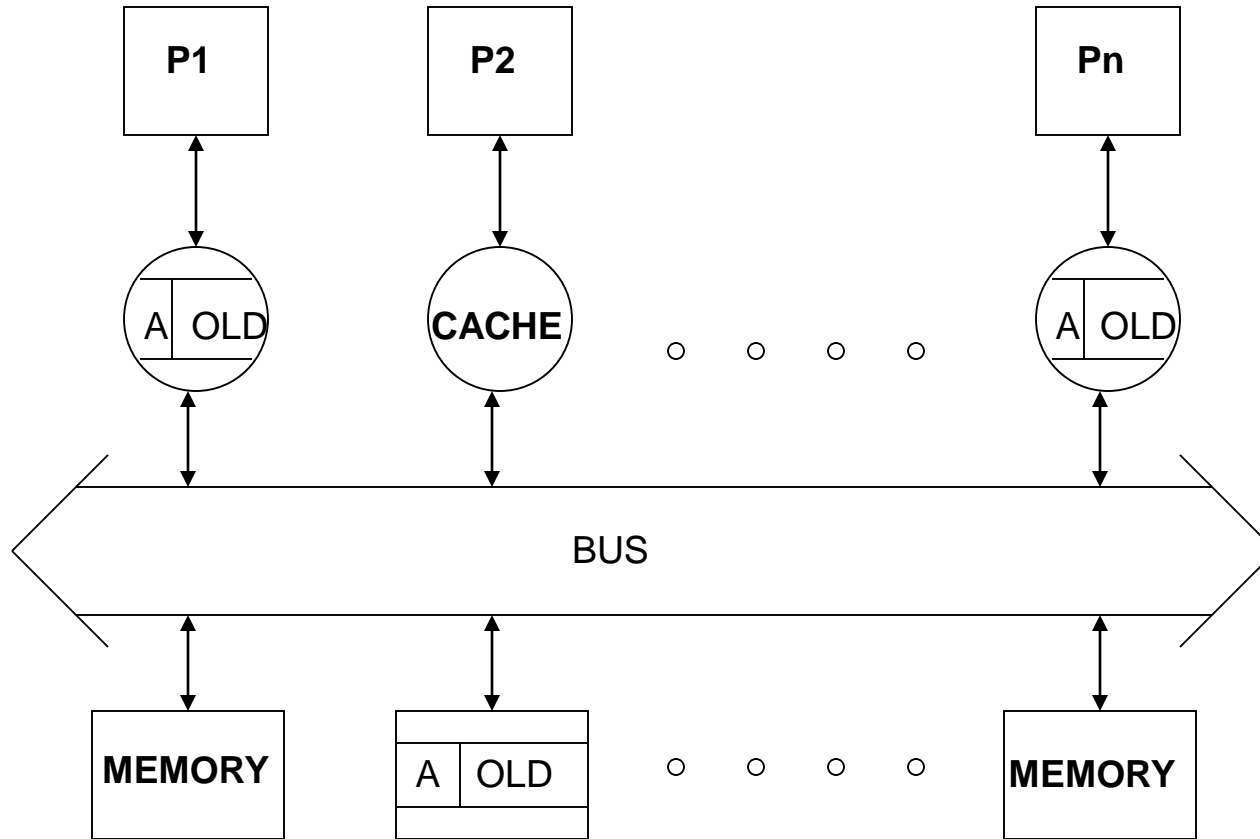

SC limits program order relaxation:

Write → Read

Write → Write

Read → Read, Write

Understanding Atomicity

A mechanism needed to propagate a write to other copies

⇒ Cache coherence protocol

Cache Coherence Protocols

How to propagate write?

Invalidate -- Remove old copies from other caches

Update -- Update old copies in other caches to new values

Understanding Atomicity - Example 1

Initially $A = B = C = 0$

P1

A = 1;

B = 1;

P2

A = 2;

C = 1;

P3

while (B != 1) {;}

while (C != 1) {;}

tmp1 = A;

P4

while (B != 1) {;}

while (C != 1) {;}

tmp2 = A;

Understanding Atomicity - Example 1

Initially A = B = C = 0

| P1 | P2 | P3 | P4 |
|--------|--------|------------------------|------------------------|
| A = 1; | A = 2; | while (B != 1) {;} | while (B != 1) {;} |
| B = 1; | C = 1; | while (C != 1) {;} | while (C != 1) {;} |
| | | tmp1 = A; 1 | tmp2 = A; 2 |

Can happen if updates of A reach P3 and P4 in different order

Coherence protocol must serialize writes to same location

(Writes to same location should be seen in same order by all)

Understanding Atomicity - Example 2

Initially $A = B = 0$

P1

A = 1

P2

while (A != 1) ; while (B != 1) ;

B = 1;

P3

tmp = A

P1

Write, A, 1

P2

Read, A, 1

Write, B, 1

P3

Read, B, 1

Read, A, ~~0~~

Can happen if read returns new value before all copies see it

SC Summary

SC limits

Program order relaxation:

Write → Read

Write → Write

Read → Read, Write

When a processor can read the value of a write

Unserialized writes to the same location

Alternative

(1) Aggressive hardware techniques proposed to get SC w/o penalty
using speculation and prefetching

But compilers still limited by SC

(2) Give up sequential consistency

Use relaxed models

Classification for Relaxed Models

Typically described as system optimizations - **system-centric**

Optimizations

Program order relaxation:

Write → Read

Write → Write

Read → Read, Write

Read others' write early

Read own write early

All models provide safety net

All models maintain uniprocessor data and control dependences,
write serialization

Some System-Centric Models

| Relaxation: | W → R Order | W → W Order | R → RW Order | Read Others' Write Early | Read Own Write Early | Safety Net |
|-------------|----------------|----------------|-----------------|-----------------------------|-------------------------|------------------------------|
| IBM 370 | ✓ | | | | | serialization instructions |
| TSO | ✓ | | | | ✓ | RMW |
| PC | ✓ | | | ✓ | ✓ | RMW |
| PSO | ✓ | ✓ | | | ✓ | RMW, STBAR |
| WO | ✓ | ✓ | ✓ | | ✓ | synchronization |
| RCsc | ✓ | ✓ | ✓ | | ✓ | release, acquire, nsync, RMW |
| RCpc | ✓ | ✓ | ✓ | ✓ | ✓ | release, acquire, nsync, RMW |
| Alpha | ✓ | ✓ | ✓ | | ✓ | MB, WMB |
| RMO | ✓ | ✓ | ✓ | | ✓ | various MEMBARs |
| PowerPC | ✓ | ✓ | ✓ | ✓ | ✓ | SYNC |

System-Centric Models: Assessment

System-centric models provide higher performance than SC

BUT **3P** criteria

Programmability?

Lost intuitive interface of SC

Portability?

Many different models

Performance?

Can we do better?

Need a higher level of abstraction

An Alternate Programmer-Centric View

One source of consensus

Programmers need SC to reason about programs

But SC not practical today

How about the next best thing...

A Programmer-Centric View

Specify memory model as a contract

System gives sequential consistency

IF programmer obeys certain rules

+ Programmability

+ Performance

+ Portability

The Data-Race-Free-0 Model: Motivation

Different operations have different semantics

P1

A = 23;

B = 37;

Flag = 1;

P2

while (Flag != 1) {;}

... = B;

... = A;

Flag = Synchronization; A, B = Data

Can reorder data operations

Distinguish data and synchronization

Need to

- Characterize data / synchronization
- Prove characterization allows optimizations w/o violating SC

Data-Race-Free-0: Some Definitions

Two operations conflict if

- Access same location
- At least one is a write

Data-Race-Free-0: Some Definitions (Cont.)

(Consider SC executions \Rightarrow global total order)

Two conflicting operations **race** if

- From different processors
- Execute one after another (consecutively)

P1

Write, A, 23

Write, B, 37

Write, Flag, 1

P2

Read, Flag, 0

Read, Flag, 1

Read, B, ____

Read, A, ____

Races usually “**synchronization**,” others “**data**”

Can optimize operations that *never race*

Data-Race-Free-0 (DRF0) Definition

Data-Race-Free-0 Program

All accesses distinguished as either **synchronization** or **data**

All **races** distinguished as **synchronization**

(in any SC execution)

Data-Race-Free-0 Model

Guarantees SC to data-race-free-0 programs

It is widely accepted that data races make programs hard to debug
independent of memory model (even with SC)

Distinguishing/Labeling Memory Operations

Need to distinguish/label operations at all levels

- High-level language
- Hardware

Compiler must translate language label to hardware label

Java: volatiles, synchronized

C++: atomics

Hardware: fences inserted before/after synchronization

Data-Race-Free Summary

The idea

Programmer writes data-race-free programs

System gives SC

For programmer

Reason with SC

Enhanced portability

For hardware and compiler

More flexibility

Finally, convergence on hardware and software sides

(BUT still many problems...)
