Application
Direction and Principles

- **Programming**
  - learn to use Internet for communication (with focus on implementation of networking concepts)
  - learn to build network from ground up

- **Principles and Concepts**

- **Physical**
- **Data Link**
- **Network**
- **Transport**
Network Programming

- How should two hosts communicate with each other over the Internet?
  - The “Internet Protocol” (IP)
  - Transport protocols: TCP, UDP

- How should programmers interact with the protocols?
  - Sockets API – application programming interface
  - De facto standard for network programming
Network Programming with Sockets

- Sockets API
  - An interface to the transport layer
    - Introduced in 1981 by BSD 4.1
    - Implemented as library and/or system calls
    - Similar interfaces to TCP and UDP
    - Can also serve as interface to IP (for super-user); known as “raw sockets”
How can many hosts communicate?

- Multiplex traffic with routers
- Question: How to identify the destination?
- Question: How to share bandwidth across different flows?
Identifying hosts with Addresses and Names

- IP addresses
  - Easily handled by routers/computers
  - Fixed length
  - E.g.: \texttt{128.121.146.100}

- But how do you know the IP address?
  - Internet domain names
  - Human readable, variable length
  - E.g.: \texttt{twitter.com}

- But how do you get the IP address from the domain name?
  - Domain Name System (DNS) maps between them
How can many hosts share network resources?

Solution: divide traffic into “IP packets”

- At each router, the entire packet is received, stored, and then forwarded to the next router
How can many hosts share network resources?

Solution: divide traffic into “IP packets”
- Use packet “headers” to denote which connection the packet belongs to
  - Contains src/dst address/port, length, checksum, time-to-live, protocol, flags, type-of-service, etc
Is IP enough?

- What if host runs multiple applications?
  - Use UDP: 16-bit “Port numbers” in header distinguishes traffic from different applications
- Or if content gets corrupted?
  - Use UDP: “Checksum” covering data, UDP header, and IP header detects flipped bits
- User Datagram Protocol (UDP)
  - Properties
    - Unreliable - no guaranteed delivery
    - Unordered - no guarantee of maintained order of delivery
    - Unlimited Transmission - no flow control
  - Unit of Transfer is “datagram” (a variable length packet)
Is UDP enough?

- What if network gets congested? Or packets get lost/reordered/duplicated?
- Use Transport Control Protocol (TCP)
  - Guarantees reliability, ordering, and integrity
  - Backs off when there is congestion
  - Connection-oriented (Set up connection before communicating, Tear down connection when done)
  - Gives ‘byte-stream’ abstraction to application
  - Also has ports, but different namespace from UDP

- Which one is better, TCP or UDP?
- Why not other hybrid design points?
How should we program networked apps?

- How can we compose together programs running on different machines?
  - Client-server model

- What sort of interfaces should we reveal to the programmer?
  - Sockets API
Client-Server Model

- A client initiates a request to a well-known server
  - Example: the web

```
GET index.html
(request for web page)
```

```
HTTP/1.0 200 OK...
(response, including web page)
```

- Other examples: FTP, SSH/Telnet, SMTP (email), Print servers, File servers
Client-Server Model

- Asymmetric Communication
  - Client sends requests
  - Server sends replies

- Server/Daemon
  - Well-known name and port
  - Waits for contact
  - Processes requests, sends replies

- Client
  - Initiates contact
  - Waits for response

Can you think of any network apps that are not client/server?
What interfaces to expose to programmer?

- Stream vs. Datagram sockets
  - Stream sockets
    - Abstraction: send a long stream of characters
    - Typically implemented on top of TCP
  - Datagram sockets
    - Abstraction: send a single packet
    - Typically implemented on top of UDP
Stream sockets

```c
send("This is a long sequence of text I would like to send to the other host")
```

```c
"This is a long sequence of text I would like to send to the other host" = recv(socket)
```
Datagram sockets

sendto("This is a long")
sendto("sequence of text")
sendto("I would like to send") sendto("to the other host")

"This is a long"=recvfrom(socket)
"sequence of text"=recvfrom(socket)
"I would like to send"=recvfrom(socket)
"to the other host"=recvfrom(socket)

Sockets API

"to the other host"
What specific functions to expose?

- Data structures to store information about connections and hosts
Socket Address Structure

- **IP address:**
  ```c
  struct in_addr {
    in_addr_t s_addr;  /* 32-bit IP address */
  };
  ```

- **TCP or UDP address:**
  ```c
  struct sockaddr_in {
    short sin_family;  /* e.g., AF_INET */
    ushort sin_port;  /* TCP/UDP port */
    struct in_addr;  /* IP address */
  };
  ```
Structure: `addrinfo`

- The `addrinfo` data structure (from `/usr/include/netdb.h`)
  - Canonical domain name and aliases
  - List of addresses associated with machine
  - Also address type and length information

```c
int ai_flags // Input flags
int ai_family // Address family of socket
int ai_socktype // Socket type
int ai_protocol // Protocol of socket
socklen_t ai_addrlen // Length of socket address
struct sockaddr *ai_addr // Socket address of socket
char *ai_canonname // Canonical name of service location
struct addrinfo *ai_next // Pointer to next in list
```
Address Access/Conversion Functions

```c
#include <sys/types.h>
#include <sys/socket.h>
#include <netdb.h>

int getaddrinfo(const char *restrict node,
                const char *restrict service,
                const struct addrinfo *restrict hints,
                struct addrinfo **restrict res);
```

- **Parameters**
  - `node`: host name or IP address to connect to
  - `service`: a port number ("80") or the name of a service (found /etc/services: "http")
  - `hints`: a filled out struct addrinfo
Example: `getaddrinfo`

```c
int status;
struct addrinfo hints;
struct addrinfo *servinfo; // pointer to results

memset(&hints, 0, sizeof hints); // empty struct
hints.ai_family = AF_UNSPEC; // don't care IPv4/IPv6
hints.ai_socktype = SOCK_STREAM; // TCP stream sockets

// get ready to connect
status = getaddrinfo("www.example.net", "3490", &hints, &servinfo);

// servinfo now points to a linked list of 1 or more struct addrinfos
```
What specific functions to expose?

- Data structures to store information about connections and hosts
- Functions to create a socket
Function: **socket**

```
int socket (int family, int type, int protocol);
```

- Create a socket.
  - Returns file descriptor or -1. Also sets **errno** on failure.
  - **family**: address family (namespace)
    - `AF_INET` for IPv4
    - other possibilities: `AF_INET6` (IPv6), `AF_UNIX` or `AF_LOCAL` (Unix socket), `AF_ROUTE` (routing)
  - **type**: style of communication
    - `SOCK_STREAM` for TCP (with `AF_INET`)
    - `SOCK_DGRAM` for UDP (with `AF_INET`)
  - **protocol**: protocol within family
    - typically 0
int sockfd, new_fd; /* listen on sock_fd, new
  connection on new_fd */
struct sockaddr_in my_addr;       /* my address */
struct sockaddr_in their_addr;    /* connector addr */
int sin_size;

if ((sockfd = socket(AF_INET, SOCK_STREAM, 0)) == -1){
    perror("socket");
    exit(1);
}
What specific functions to expose?

- Data structures to store information about connections and hosts
- Functions to create a socket
- Functions to establish connections
TCP Connection Setup

- Client:
  - socket
  - connect
  - connect completes

- Server:
  - socket
  - bind
  - listen
  - accept
  - connection moved to complete queue
  - connection added to incomplete queue

Synchronization (SYN) J
SYN K, acknowledge (ACK) J+1
ACK K+1

Spring 2019
Copyright ©: CS 438 Staff, University of Illinois
Function: **bind**

```c
int bind (int sockfd, struct sockaddr* myaddr, int addrlen);
```

- Bind a socket to a local IP address and port number
  - Returns 0 on success, -1 and sets `errno` on failure
  - `sockfd`: socket file descriptor (returned from `socket`)
  - `myaddr`: includes IP address and port number
    - IP address: set by kernel if value passed is `INADDR_ANY`, else set by caller
    - port number: set by kernel if value passed is 0, else set by caller
  - `addrlen`: length of address structure
    - `= sizeof (struct sockaddr_in)`
TCP and UDP Ports

- Allocated and assigned by the Internet Assigned Numbers Authority
  - see RFC 1700 (for historical purposes only)

</table>
Function: `listen`

```c
int listen (int sockfd, int backlog);
```

- Put socket into passive state (wait for connections rather than initiate a connection)
  - Returns 0 on success, -1 and sets `errno` on failure
  - `sockfd`: socket file descriptor (returned from `socket`)
  - `backlog`: bound on length of unaccepted connection queue (connection backlog); kernel will cap, thus better to set high
  - Example:
    ```c
    if (listen(sockfd, BACKLOG) == -1) {
      perror("listen");
      exit(1);
    }
    ```
Functions: `accept`

```c
int accept (int sockfd, struct sockaddr* cliaddr, int* addrlen);
```

- Block waiting for a new connection
  - Returns file descriptor or -1 and sets `errno` on failure
  - `sockfd`: socket file descriptor (returned from `socket`)
  - `cliaddr`: IP address and port number of client (returned from call)
  - `addrlen`: length of address structure = pointer to `int` set to `sizeof (struct sockaddr_in)`

- `addrlen` is a `value-result` argument
  - the caller passes the size of the address structure, the kernel returns the size of the client’s address (the number of bytes written)
Functions: **accept**

```c
sin_size = sizeof(struct sockaddr_in);
if (((new_fd = accept(sockfd, (struct sockaddr*)
        &their_addr, &sin_size)) == -1) {
    perror("accept");
    continue;
}
```

How does the server know which client it is?
- `their_addr.sin_addr` contains the client’s IP address
- `their_addr.port` contains the client’s port number

```c
printf("server: got connection from %s\n",
       inet_ntoa(their_addr.sin_addr));
```
Functions: **accept**

**Notes**
- After `accept()` returns a new socket descriptor, I/O can be done using `read()` and `write()`
- Why does `accept()` need to return a new descriptor?
Example: Server

```c
my_addr.sin_family = AF_INET; /* host byte order */
my_addr.sin_port = htons(MYPORT); /* short, network byte order */
my_addr.sin_addr.s_addr = htonl(INADDR_ANY);
/* automatically fill with my IP */
bzero(&(my_addr.sin_zero), 8); /* zero struct */

if (bind(sockfd, (struct sockaddr *)&my_addr,
         sizeof(struct sockaddr)) == -1) {
    perror("bind");
    exit(1);
}
```
Example: Server

```c
if (listen(sockfd, BACKLOG) == -1) {
perror("listen");
exit(1);
}
```

```c
#include <sys/socket.h>
#include <netinet/in.h>

while(1) { /* main accept() loop */
    sin_size = sizeof(struct sockaddr_in);
    if ((new_fd = accept(sockfd, (struct sockaddr*)
                    &their_addr,&sin_size)) == -1) {
        perror("accept");
        continue;
    }
    printf("server: got connection from %s\n",
           inet_ntoa(their_addr.sin_addr));
```
Function: **connect**

```c
int connect (int sockfd, struct sockaddr* servaddr, int addrlen);
```

- Connect to another socket.
  - Returns 0 on success, -1 and sets `errno` on failure
  - `sockfd`: socket file descriptor (returned from `socket`)
  - `servaddr`: IP address and port number of server
  - `addrlen`: length of address structure
    - `= sizeof (struct sockaddr_in)`

- Can use with UDP to restrict incoming datagrams and to obtain asynchronous errors
Example: Client

define receive:

their_addr.sin_family = AF_INET; /* interp’d by host */
their_addr.sin_port = htons (PORT);
their_addr.sin_addr = *((struct in_addr*)he->h_addr);
bzero (&(their_addr.sin_zero), 8);
/* zero rest of struct */
if (connect (sockfd, (struct sockaddr*)&their_addr,
            sizeof (struct sockaddr)) == -1) {
    perror ("connect");
    exit (1);
}
What specific functions to expose?

- Data structures to store information about connections and hosts
- Functions to create a socket
- Functions to establish connections
- Functions to send and receive data
TCP Connection Example

client

socket
connect
write
read

server

socket
bind
listen
accept
read
write
int write (int sockfd, char* buf, size_t nbytes);

Write data to a stream (TCP) or “connected” datagram (UDP) socket

- Returns number of bytes written or -1 and sets errno on failure
- sockfd: socket file descriptor (returned from socket)
- buf: data buffer
- nbytes: number of bytes to try to write
- Example:

```c
if((w = write(fd, buf, sizeof(buf))) < 0) {
    perror("write");
    exit(1);
}
```
Functions: **write**

```c
int write (int sockfd, char* buf, size_t nbytes);
```

**Notes**

- **write** blocks waiting for data from the client
- **write** may not write all bytes asked for
  - Does not guarantee that `sizeof(buf)` is written
  - This is not an error
  - Simply continue writing to the device
- **Some reasons for failure or partial writes**
  - Process received interrupt or signal
  - Kernel resources unavailable (e.g., buffers)
/* Write "n" bytes to a descriptor */
ssize_t writen(int fd, const void *ptr, size_t n) {
    size_t nleft;
    ssize_t nwritten;
    nleft = n;
    while (nleft > 0) {
        if ((nwritten = write(fd, ptr, nleft)) < 0) {
            if (nleft == n) {
                return(-1); /* error, return -1 */
            } else {
                break; /* error, return amount written so far */
            }
        } else {
            if (nwritten == 0) break;
            nleft -= nwritten;
        }
    }
    return(n - nleft); /* return >= 0 */
}
int send(int sockfd, const void * buf, size_t nbytes, int flags);

- Send data un a stream (TCP) or “connected” datagram (UDP) socket
  - Returns number of bytes written or -1 and sets errno on failure
  - sockfd: socket file descriptor (returned from socket)
  - buf: data buffer
  - nbytes: number of bytes to try to write
  - flags: control flags
    - MSG_PEEK: get data from the beginning of the receive queue without removing that data from the queue

- Example
  ```
  len = strlen(msg);
  bytes_sent = send(sockfd, msg, len, 0);
  ```

Functions: \texttt{read}

\begin{verbatim}
int read (int sockfd, char* buf, size_t nbytes);
\end{verbatim}

- Read data from a stream (TCP) or “connected” datagram (UDP) socket
  - Returns number of bytes read or -1, sets \texttt{errno} on failure
  - Returns 0 if socket closed
  - \texttt{sockfd}: socket file descriptor (returned from \texttt{socket})
  - \texttt{buf}: data buffer
  - \texttt{nbytes}: number of bytes to try to read

- Example
  \begin{verbatim}
  if((r = read(newfd, buf, sizeof(buf))) < 0) {
    perror("read"); exit(1);
  }
  \end{verbatim}
Functions: `read`

```c
int read (int sockfd, char* buf, size_t nbytes);
```

Notes
- `read` blocks waiting for data from the client
- `read` may return less than asked for
  - Does not guarantee that `sizeof(buf)` is read
  - This is not an error
  - Simply continue reading from the device
Example: `readn`

```c
/* Read "n" bytes from a descriptor */
ssize_t readn(int fd, void *ptr, size_t n) {
    size_t nleft;
    ssize_t nread;
    nleft = n;
    while (nleft > 0) {
        if ((nread = read(fd, ptr, nleft)) < 0) {
            if (nleft == n)
                return(-1); /* error, return -1 */
            else
                break; /* error, return amt read */
        } else
            if (nread == 0)
                break; /* EOF */
        nleft -= nread;
        ptr += nread;
    }
    return(n - nleft); /* return >= 0 */
}
```

read returned a potential error

0 bytes were read

Update number of bytes left to read and pointer into buffer
Functions: `recv`

```
int recv(int sockfd, void *buf, size_t nbytes, int flags);
```

- Read data from a stream (TCP) or “connected” datagram (UDP) socket
  - Returns number of bytes read or -1, sets `errno` on failure
  - Returns 0 if socket closed
  - `sockfd`: socket file descriptor (returned from `socket`)
  - `buf`: data buffer
  - `nbytes`: number of bytes to try to read
  - `flags`: see man page for details; typically use 0
Functions: `recv`

```c
int read (int sockfd, char* buf, size_t nbytes);
```

**Notes**

- `read` blocks waiting for data from the client but does not guarantee that `sizeof(buf)` is read

- Example
  ```c
  if((r = read(newfd, buf, sizeof(buf))) < 0) {
      perror("read"); exit(1);
  }
  ```
Sending and Receiving Data

- Datagram sockets aren't connected to a remote host
  - What piece of information do we need to give before we send a packet?
  - The destination/source address!
UDP Connection Example

client

socket
sendto
recvfrom

server

socket
bind
recvfrom
sendto
recvfrom
Functions: **sendto**

```
int sendto (int sockfd, char* buf, size_t nbytes, int flags, struct sockaddr* destaddr, int addrlen);
```

- Send a datagram to another UDP socket
  - Returns number of bytes written or -1 and sets `errno` on failure
  - `sockfd`: socket file descriptor (returned from `socket`)
  - `buf`: data buffer
  - `nbytes`: number of bytes to try to read
  - `flags`: see man page for details; typically use 0
  - `destaddr`: IP address and port number of destination socket
  - `addrlen`: length of address structure
    - `= sizeof (struct sockaddr_in)`
Functions: **sendto**

```c
int sendto (int sockfd, char* buf, size_t nbytes, int flags, struct sockaddr* destaddr, int addrlen);

Example
```

```c
n = sendto(sock, buf, sizeof(buf), 0,(struct sockaddr *) &from,fromlen);
if (n < 0)
    perror("sendto");
    exit(1);
}
```
Functions: `recvfrom`

```c
int recvfrom (int sockfd, char* buf, size_t nbytes, int flags, struct sockaddr* srcaddr, int* addrlen);
```

- **Read a datagram from a UDP socket.**
  - Returns number of bytes read (0 is valid) or -1 and sets `errno` on failure
  - `sockfd`: socket file descriptor (returned from `socket`)
  - `buf`: data buffer
  - `nbytes`: number of bytes to try to read
  - `flags`: see man page for details; typically use 0
  - `srcaddr`: IP address and port number of sending socket (returned from call)
  - `addrlen`: length of address structure = pointer to `int` set to `sizeof (struct sockaddr_in)`
Functions: `recvfrom`

```c
int recvfrom (int sockfd, char* buf, size_t nbytes, int flags, struct sockaddr* srcaddr, int* addrlen);
```

- **Example**

```c
n = recvfrom(sock, buf, 1024, 0, (struct sockaddr *)&from,&fromlen);
if (n < 0) {
    perror("recvfrom");
    exit(1);
}
```
What specific functions to expose?

- Data structures to store information about connections and hosts
- Functions to **create** a socket
- Functions to **establish** connections
- Functions to **send** and **receive** data
- Functions to **teardown** connections
int close (int sockfd);

- Close a socket
  - Returns 0 on success, -1 and sets errno on failure
  - sockfd: socket file descriptor (returned from socket)

- Closes communication on socket in both directions
  - All data sent before close are delivered to other side (although this aspect can be overridden)

- After close, sockfd is not valid for reading or writing
Functions: `shutdown`

```c
int shutdown (int sockfd, int howto);
```

- Force termination of communication across a socket in one or both directions
  - Returns 0 on success, -1 and sets `errno` on failure
  - `sockfd`: socket file descriptor (returned from `socket`)
  - `howto`:
    - `SHUT_RD` to stop reading
    - `SHUT_WR` to stop writing
    - `SHUT_RDWR` to stop both

- `shutdown` overrides the usual rules regarding duplicated sockets, in which TCP teardown does not occur until all copies have closed the socket
Note on close vs. shutdown

- **close()**: closes the socket but the connection is still open for processes that shares this socket
  - The connection stays opened both for read and write

- **shutdown()**: breaks the connection for all processes sharing the socket
  - A read will detect **EOF**, and a write will receive **SIGPIPE**
  - **shutdown()** has a second argument how to close the connection:
    - 0 means to disable further reading
    - 1 to disable writing
    - 2 disables both
One tricky issue…

- Different processor architectures store data in different “byte orderings”
  - What is 200 in binary?
  - 1100 1001?
  - or
  - 1001 1100?
One tricky issue…

- Big Endian vs. Little Endian
  - Little Endian (Intel, DEC):
    - Least significant byte of word is stored in the lowest memory address
  - Big Endian (Sun, SGI, HP, PowerPC):
    - Most significant byte of word is stored in the lowest memory address
  - Example: \texttt{128.2.194.95}

<table>
<thead>
<tr>
<th></th>
<th>Big Endian</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>128</td>
<td>2</td>
<td>194</td>
<td>95</td>
</tr>
<tr>
<td>Little Endian</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>95</td>
<td>194</td>
<td>2</td>
<td>128</td>
</tr>
</tbody>
</table>

Where did the term “endian” come from?
One tricky issue…

- Big Endian vs. Little Endian: which should we use for networked communication?
  - Network Byte Order = Big Endian
    - Allows both sides to communicate
    - Must be used for some data (i.e. IP Addresses)
  - What about ordering within bytes?
    - Most modern processors agree on ordering within bytes
Converting byte orderings

Solution: use byte ordering functions to convert.

```c
int m, n;
short int s,t;

m = ntohl (n)  // net-to-host long (32-bit) translation
s = ntohs (t)  // net-to-host short (16-bit) translation
n = htonl (m)  // host-to-net long (32-bit) translation
t = htons (s)  // host-to-net short (16-bit) translation
```
Why Can’t Sockets Hide These Details?

- Dealing with endian differences is tedious
  - Couldn’t the socket implementation deal with this
  - ... by swapping the bytes as needed?

- No, swapping depends on the data type
  - Two-byte short int: (byte 1, byte 0) vs. (byte 0, byte 1)
  - Four-byte long int: (byte 3, byte 2, byte 1, byte 0) vs. (byte 0, byte 1, byte 2, byte 3)
  - String of one-byte charters: (char 0, char 1, char 2, ...) in both cases

- Socket layer doesn’t know the data types
  - Sees the data as simply a buffer pointer and a length
  - Doesn’t have enough information to do the swapping
Advanced Sockets: `signal`

- Problem: Socket at other end is closed
  - Write to your end generates `SIGPIPE`
  - This signal kills the program by default!

```c
signal (SIGPIPE, SIG_IGN);
```

- Call at start of main in server
- Allows you to ignore broken pipe signals
- Can ignore or install a proper signal handler
- Default handler exits (terminates process)
Advanced Sockets

Problem: How come I get "address already in use" from `bind()`?

- You have stopped your server, and then re-started it right away
- The sockets that were used by the first incarnation of the server are still active
Advanced Sockets: 

**setsockopt**

```c
int yes = 1;
setsockopt (fd, SOL_SOCKET, 
           SO_REUSEADDR, (char *) &yes, sizeof (yes));
```

- Call just before `bind()`
- Allows bind to succeed despite the existence of existing connections in the requested TCP port
- Connections in limbo (e.g. lost final ACK) will cause bind to fail
How to handle concurrency?

- Process requests serially
  - Slow – what if you’re processing another request? What if you’re blocked on `read()`?
How can a UDP server service multiple ports simultaneously?
UDP Server: Servicing Two Ports

```c
int s1; /* socket descriptor 1 */
int s2; /* socket descriptor 2 */

/* 1) create socket s1 */
/* 2) create socket s2 */
/* 3) bind s1 to port 2000 */
/* 4) bind s2 to port 3000 */

while(1) {
    recvfrom(s1, buf, sizeof(buf), ...);
    /* process buf */
    recvfrom(s2, buf, sizeof(buf), ...);
    /* process buf */
}
```

What problems does this code have?
How to handle concurrency?

- Process requests serially
  - Slow – what if you’re processing another request? What if you’re blocked on `accept()`?

- Multiple threads/processes (e.g. Apache, Chrome)
  - Each thread/process handles one request
    - `fork()`, `pthreads`

- Synchronous I/O (e.g. Squid web proxy cache)
  - Maintain a “set” of file descriptors, whenever one has an “event”, process it and put it back onto the set
    - `select()`, `poll()`
Select

```c
int select (int num_fds, fd_set* read_set, fd_set* write_set, fd_set* except_set, struct timeval* timeout);
```

- Wait for readable/writable file descriptors.
- Return:
  - Number of descriptors ready
  - -1 on error, sets `errno`
- Parameters:
  - `num_fds`:
    - number of file descriptors to check, numbered from 0
  - `read_set, write_set, except_set`:
    - Sets (bit vectors) of file descriptors to check for the specific condition
  - `timeout`:
    - Time to wait for a descriptor to become ready
File Descriptor Sets

```c
int select (int num_fds, fd_set* read_set,
           fd_set* write_set, fd_set* except_set, struct timeval* timeout);
```

- **Bit vectors**
  - Only first `num_fds` checked
  - Macros to create and check sets

```c
fds_set myset;
void FD_ZERO (&myset); /* clear all bits */
void FD_SET (n, &myset);  /* set bits n to 1 */
void FD_CLEAR (n, &myset); /* clear bit n */
int FD_ISSET (n, &myset); /* is bit n set? */
```
File Descriptor Sets

- Three conditions to check for
  - Readable:
    - Data available for reading
  - Writable:
    - Buffer space available for writing
  - Exception:
    - Out-of-band data available (TCP)
Time structure

Number of seconds since midnight, January 1, 1970 GMT

```c
struct timeval {
    long tv_sec;    /* seconds */
    long tv_usec;   /* microseconds */
};
```

unix will have its own "Y2K" problem one second after 10:14:07pm, Monday January 18, 2038 (will appear to be 3:45:52pm, Friday December 13, 1901)
Select

- High-resolution sleep function
  - All descriptor sets NULL
  - Positive timeout
- Wait until descriptor(s) become ready
  - At least one descriptor in set
  - timeout NULL
- Wait until descriptor(s) become ready or timeout occurs
  - At least one descriptor in set
  - Positive timeout
- Check descriptors immediately (poll)
  - At least one descriptor in set
  - 0 timeout

Which file descriptors are set and what should the timeout value be?
Select: Example

```c
fd_set my_read;
FD_ZERO(&my_read);
FD_SET(0, &my_read);

if (select(1, &my_read, NULL, NULL) == 1) {
    assert(FD_ISSET(0, &my_read);
    /* data ready on stdin */
}
```

What went wrong: after select indicates data available on a connection, read returns no data?
Wait 2.5 seconds for something to appear on standard input
select() vs. poll()

Which to use?

- **BSD-family** (e.g., FreeBSD, MacOS)
  - `poll()` just calls `select()` internally
- **System V family** (e.g., AT&T Unix)
  - `select()` just calls `poll()` internally
Concurrent programming with Posix Threads (pthreads)

- Thread management
  - Creating, detaching, joining, etc.
  - Set/query thread attributes
- Mutexes
  - Synchronization
- Condition variables
  - Communications between threads that share a mutex
