Tuesday’s key concepts

Distributional hypothesis

Distributional similarities:
- word-context matrix
- representing words as vectors
- positive PMI
- computing the similarity of word vectors
What does ‘bank’ mean?

- a financial institution
  *(US banks have raised interest rates)*

- a particular branch of a financial institution
  *(the bank on Green Street closes at 5pm)*

- the bank of a river
  *(In 1927, the bank of the Mississippi flooded)*

- a ‘repository’
  *(I donate blood to a blood bank)*
Lexicon entries

**bank**

1. noun: the land alongside or sloping down to a river or lake: *willows lined the riverbank.*
2. noun: a slope, mass, or mound of a particular substance: *a bank of clouds | a bank of snow.*
   - an elevation in the seabed or a riverbed; a mudbank or sandbank.
   - a transverse slope given to a road, railroad, or sports track to enable vehicles or runners to maintain speed around a curve.
   - the sideways tilt of an aircraft when turning in flight: *flying with small amounts of bank.*
3. noun: a set or series of similar things, esp. electrical or electronic devices, grouped together in rows: *the DF had big banks of lights and speakers on either side of his console.*
   - a tier of oars: *the early ships had only twenty-five oars in each bank.*
4. noun: the cushion of a pool table: [as adj.] *a bank shot.*

**bank**

noun: a financial establishment that invests money deposited by customers, pays it out when required, makes loans at interest, and exchanges currency: *I paid the money straight into my bank.*
- a stock of something available for use when required: *a blood bank | building a bank of test items is the responsibility of teachers.*
- a place where something may be safely kept: *the computer’s memory bank.*
- *(the bank)* the store of money or tokens held by the banker in some gambling or board games.
- the person holding this store; the banker.
- Brit. a site or receptacle where something may be deposited for recycling: *a paper bank.*
Some terminology

**Word forms:** *runs, ran, running; good, better, best*

Any, possibly inflected, form of a word
(i.e. what we talked about in morphology)

**Lemma** *(citation/dictionary form): run*

A basic word form (e.g. infinitive or singular nominative noun) that is used to represent all forms of the same word.
(i.e. the form you’d search for in a dictionary)

**Lexeme:** \textsc{Run(V)}, \textsc{Good(A)}, \textsc{Bank}^1(N), \textsc{Bank}^2(N)

An abstract representation of a word (and all its forms), with a part-of-speech and a set of related word senses.
(Often just written (or referred to) as the lemma, perhaps in a different font)

**Lexicon:**

A (finite) list of lexemes
Trying to make sense of senses

Polysemy:
A lexeme is polysemous if it has different related senses

bank = financial institution or building

Homonyms:
Two lexemes are homonyms if their senses are unrelated, but they happen to have the same spelling and pronunciation

bank = (financial) bank or (river) bank
Relations between senses

**Symmetric** relations:

**Synonyms**: couch/sofa
Two lemmas with the **same** sense

**Antonyms**: cold/hot, rise/fall, in/out
Two lemmas with the **opposite** sense

**Hierarchical** relations:

**Hypernyms** and **hyponyms**: pet/dog
The hyponym (dog) is **more specific** than the hypernym (pet)

**Holonyms** and **meronyms**: car/wheel
The meronym (wheel) is a **part of** the holonym (car)
WordNet
WordNet

Very large **lexical database of English:**
110K nouns, 11K verbs, 22K adjectives, 4.5K adverbs
(WordNets for many other languages exist or are under construction)

**Word senses** grouped into **synonym sets** ("synsets")
linked into a **conceptual-semantic hierarchy**
81K noun synsets, 13K verb synsets, 19K adj. synsets, 3.5K adv synsets
Avg. # of senses: 1.23 nouns, 2.16 verbs, 1.41 adj, 1.24 adverbs

**Conceptual-semantic relations:** **hyponym/hypernym**
also holonym/meronym
Also lexical relations, in particular lemmatization

Available at http://wordnet.princeton.edu
A WordNet example

Word to search for: bass

Display Options: (Select option to change) ▼ Change

Key: "S:" = Show Synset (semantic) relations, "W:" = Show Word (lexical) relations

Noun

• S: (n) bass (the lowest part of the musical range)
• S: (n) bass, bass part (the lowest part in polyphonic music)
• S: (n) bass, basso (an adult male singer with the lowest voice)
• S: (n) sea bass, bass (the lean flesh of a saltwater fish of the family Serranidae)
• S: (n) freshwater bass, bass (any of various North American freshwater fish with lean flesh (especially of the genus Micropterus))
• S: (n) bass, bass voice, basso (the lowest adult male singing voice)
• S: (n) bass (the member with the lowest range of a family of musical instruments)
• S: (n) bass (nontechnical name for any of numerous edible marine and freshwater spiny-finned fishes)

Adjective

• S: (adj) bass, deep (having or denoting a low vocal or instrumental range) "a deep voice"; "a bass voice is lower than a baritone voice"; "a bass clarinet"

WordNet home page
Hierarchical synset relations: nouns

**Hypernym/hyponym** (between concepts)
The more general ‘*meal*’ is a hypernym of the more specific ‘*breakfast*’

**Instance hypernym/hyponym** (between concepts and instances)
*Austen* is an instance hyponym of *author*

**Member holonym/meronym** (groups and members)
*professor* is a member meronym of (a university’s) *faculty*

**Part holonym/meronym** (wholes and parts)
*wheel* is a part meronym of (is a part of) *car*.

**Substance meronym/holonym** (substances and components)
*flour* is a substance meronym of (is made of) *bread*
Hierarchical synset relations: verbs

**Hypernym/troponym** (between events):
*travel/fly, walk/stroll*

*Flying* is a troponym of *traveling*:
it denotes **a specific manner** of *traveling*

**Entailment** (between events):
*snore/sleep*

*Snoring entails (presupposes) sleeping*
WordNet Hypernyms and Hyponyms

- **S: (n) bass** (the lowest part of the musical range)
  - *direct hypernym* / *inherited hypernym* / *sister term*
    - **S: (n) pitch** (the property of sound that varies with variation in the frequency of vibration)
    - **S: (n) sound property** (an attribute of sound)
    - **S: (n) property** (a basic or essential attribute shared by all members of a class) "a study"
    - **S: (n) attribute** (an abstraction belonging to or characteristic of an entity)
    - **S: (n) abstraction, abstract entity** (a general concept formed by extracting common characteristics of a group of things)
    - **S: (n) entity** (that which is perceived or known or inferred to have...
  - **S: (n) bass**, **bass part** (the lowest part in polyphonic music)
    - *direct hypernym* / *full hypernym*
      - **S: (n) ground bass** (a short melody in the bass that is constantly repeated)
      - **S: (n) figured bass, basso continuo, continuo, thorough bass** (a bass part written out in full and accented)
    - *direct hypernym* / *inherited hypernym* / *sister term*
      - **S: (n) part, voice** (the melody carried by a particular voice or instrument in polyphonic music) "he..."
Thesaurus-based similarity
Thesaurus-based word similarity

Instead of using distributional methods, rely on a resource like WordNet to compute word similarities.

Problem: each word may have multiple entries in WordNet, depending on how many senses it has. We often just assume that the similarity of two words is equal to the similarity of their two most similar senses.

NB: There are a few recent attempts to combine neural embeddings with the information encoded in resources like WordNet. Here, we’ll just go quickly over some classic approaches.
Thesaurus-based word similarity

Basic idea:
A thesaurus like WordNet contains all the information needed to compute a semantic distance metric.

Simplest instance: compute distance in WordNet
\[ \text{sim}(s, s') = -\log \text{pathlen}(s, s') \]
\text{pathlen}(s, s') \text{ number of edges in shortest path between } s \text{ and } s' \]

Note: WordNet nodes are synsets (=word senses).
Applying this to words \( w, w' \):
\[ \text{sim}(w, w') = \max \text{ sim}(s, s') \]
\[ s \in Senses(w) \]
\[ s' \in Senses(w') \]
WordNet path lengths

The path length (distance) \( pathlen(s, s') \) between two senses \( s, s' \) is the length of the (shortest) path between them.
The lowest common subsumer

The *lowest common subsumer* (ancestor) $LCS(s, s')$ of two senses $s$, $s'$ is the lowest common ancestor node in the hierarchy.
WordNet path lengths

A few examples:

pathlen(nickel, dime) = 2
pathlen(nickel, money) = 5
pathlen(nickel, budget) = 7

But do we really want the following?

pathlen(nickel, coin) < pathlen(nickel, dime)
pathlen(nickel, Richter scale) = pathlen(nickel, budget)
Information-content similarity

**Basic idea:** Add **corpus statistics** to thesaurus hierarchy

For each concept/sense $s$ (synset node in WordNet), define:
- $\text{words}(s)$: the set of words subsumed by (=below) $s$.
  
  *All words will be subsumed by the root of the hierarchy*

- $P(s)$: the probability that a random word in the corpus is an instance of $s$
  
  $$P(s) = \frac{\sum_{w \in \text{words}(s)} c(w)}{N}$$

  (Either use a sense-tagged corpus, or count each word as one instance of each of its possible senses)

- This defines the **Information content** of a sense $s$:
  $$IC(s) = -\log P(s)$$
P(s) and IC(s): examples

**entity**
- *hill*  
  - $p=0.0000189 $  
  - $IC=15.7$
- *coast*  
  - $p=0.000216 $  
  - $IC=15.5$

**geological formation**
- $p=0.00176 $  
  - $IC=9.15$

- $p=0.395 $  
  - $IC=1.3$
Using LCS to compute similarity

Resnik (1995)’s similarity metric:

\[ \text{sim}_{\text{Resnik}}(s, s') = -\log P(\text{LCS}(s, s')) \]

The underlying intuition:
- If \( s_{\text{LCS}} = \text{LCS}(s, s') \) is the root of the hierarchy, \( P(s_{\text{LCS}}) = 1 \)
- The lower \( s_{\text{LCS}} \) is in the hierarchy,
  the more specific it is, and the lower \( P(s_{\text{LCS}}) \) will be.

\( \text{LCS}(\text{car, banana}) = \text{physical entity} \)
\( \text{LCS}(\text{nickel, dime}) = \text{coin} \)

Problem: this does not take into account how different \( s, s' \) are
\( \text{LCS}(\text{thing, object}) = \text{physical entity} = \text{LCS}(\text{car, banana}) \)
Better similarity metrics

Lin (1998)’s similarity:
\[ sim_{Lin}(s,s’) = 2 \times \log P(s_{LCS}) / [ \log P(s) + \log P(s’) ] \]

Jiang & Conrath (1997) ’s distance
\[ dist_{JC}(s,s’) = 2 \times \log P(s_{LCS}) - [ \log P(s) + \log P(s’) ] \]
\[ sim_{JC}(s,s’) = 1/dist_{JC}(s, s’) \]

(NB: you don’t have to memorize these for the exam…)}
Problems with thesaurus-based similarity

We need to have a thesaurus! (not available for all languages)

We need to have a thesaurus that contains the words we’re interested in.

We need a thesaurus that captures a rich hierarchy of hypernyms and hyponyms.

Most thesaurus-based similarities depend on the specifics of the hierarchy that is implement in the thesaurus.
Learning hyponym relations

If we don’t have a thesaurus, can we learn that Corolla is a kind of car?

Certain **phrases and patterns** indicate hyponym relations: Hearst(1992)

**Enumerations:** *cars such as the Corolla, the Civic, and the Vibe,*
**Appositives:** *the Corolla, a popular car…*

We can also **learn these patterns** if we have some **seed examples of hyponym relations** (e.g. from WordNet):

1. **Take all hyponym/hypernym pairs from WordNet (e.g. car/vehicle)**
2. **Find all sentences that contain both, and identify patterns**
3. **Apply these patterns to new data** to get new hyponym/hypernym pairs
Word Sense Disambiguation
What does this word mean?

This **plant** needs to be **watered** each day.
⇒ **living plant**

This **plant** manufactures **1000 widgets** each day.
⇒ **factory**

Word Sense Disambiguation (WSD):
Identify the sense of content words (nouns, verbs, adjectives) in context (assuming a fixed inventory of word senses)

Applications: machine translation, question answering, information retrieval, text classification
The data

<table>
<thead>
<tr>

WSD evaluation

Evaluation metrics:
- **Accuracy**: How many instances of the word are tagged with their correct sense?
- **Precision and recall**: How many instances of each sense did we predict/recover correctly?

Baseline accuracy:
- Choose the **most frequent sense** per word
  - WordNet: take the first (=most frequent) sense
- **Lesk algorithm** (see below)

Upper bound accuracy:
- **Inter-annotator agreement**: how often do two people agree
  - ~75-80% for all words task with WordNet, ~90% for simple binary tasks
- **Pseudo-word task**: Replace all occurrences of words $w_a$ and $w_b$ (*door*, *banana*) with a nonsense word $w_{ab}$ (*banana-door*).
Dictionary-based WSD: Lesk algorithm

(Lesk 1986)
Dictionary-based methods

We often don’t have a labeled corpus, but we might have a dictionary/thesaurus that contains glosses and examples:

**bank1**
Gloss: a financial institution that accepts deposits and channels the money into lending activities
Examples: “he cashed the check at the bank”, “that bank holds the mortgage on my home”

**bank2**
Gloss: sloping land (especially the slope beside a body of water)
Examples: “they pulled the canoe up on the bank”, “he sat on the bank of the river and watched the current”
The Lesk algorithm

Basic idea: Compare the context with the dictionary definition of the sense.
  Assign the dictionary sense whose gloss and examples are most similar to the context in which the word occurs.

Compare the **signature of a word in context** with the **signatures of its senses in the dictionary**
Assign the sense that is **most similar** to the context

**Signature** = set of content words
(in examples/gloss or in context)

**Similarity** = size of intersection of context signature and sense signature
Sense signatures (dictionary)

**bank1:**
Gloss: a financial institution that accepts deposits and channels the money into lending activities
Examples: “he cashed the check at the bank”, “that bank holds the mortgage on my home”

\[ \text{Signature(bank1)} = \{ \text{financial, institution, accept, deposit, channel, money, lend, activity, cash, check, hold, mortgage, home} \} \]

**bank2:**
Gloss: sloping land (especially the slope beside a body of water)
Examples: “they pulled the canoe up on the bank”, “he sat on the bank of the river and watched the current”

\[ \text{Signature(bank2)} = \{ \text{slope, land, body, water, pull, canoe, sit, river, watch, current} \} \]
Signature of target word

Test sentence: “The bank refused to give me a loan.”

**Simplified Lesk:** Overlap between sense signature and (simple) signature of the target word:
Target signature = words in context: \{refuse, give, loan\}

**Original Lesk:** Overlap between sense signature and augmented signature of the target word
Augmented target signature with signatures of words in context
\{refuse, reject, request, ..., give, gift, donate, ..., loan, money, borrow, ...\}
Lesk algorithm: Summary

The Lesk algorithm requires an electronic dictionary of word senses (e.g. WordNet) and a lemmatizer.

It does not use any machine learning, but it is still a useful baseline.
WSD as a learning problem
WSD as a learning problem

Supervised:
- You have a (large) corpus annotated with word senses
- Here, WSD is a standard supervised learning task

Semi-supervised (bootstrapping) approaches:
- You only have very little annotated data
  (and a lot of raw text)
- Here, WSD is a semi-supervised learning task
WSD as a (binary) classification task

If $w$ has two different senses, we can treat WSD for $w$ as a binary classification problem:

Does this occurrence of $w$ have sense A or sense B?

If $w$ has multiple senses, we are dealing with a multiclass classification problem.

We can use labeled training data to train a classifier.

Labeled = each instance of $w$ is marked as A or B.
This is a kind of supervised learning
Designing a WSD classifier

We represent each occurrence of the word $w$ as a feature vector $w$

Now the elements of $w$ capture the *specific* context of the token $w$

In distributional similarities, $w$ provides a summary of all the contexts in which $w$ occurs in the training corpus.
Implementing a WSD classifier

**Basic insight:** The *sense of a word* in a context depends on the *words in its context.*

**Features:**
- **Which words in context:** all words, all/some content words
- **How large is the context?** sentence, prev/following 5 words
- **Do we represent context as bag of words** (unordered set of words) or do we care about the *position* of words (preceding/following word)?
- **Do we care about POS tags?**
- **Do we represent words as they occur in the text or as their lemma** (dictionary form)?
A decision list is an ordered list of yes-no questions

\( bass_1 = \text{fish} \) vs. \( bass_2 = \text{music} \):

1. Does ‘fish’ occur in window? - Yes. => bass1
2. Is the previous word ‘striped ’? - Yes. => bass1
3. Does ‘guitar’ occur in window? - Yes. => bass2
4. Is the following word ‘player’? - Yes. => bass2

Learning a decision list for a word with two senses:

- Define a **feature set**: what kind of questions do you want to ask?
- Enumerate all features (questions) the training data gives answers for
- Score each feature:
  \[
  \text{score}(f_i) = \log \left( \frac{P(\text{sense}_1|f_i)}{P(\text{sense}_2|f_i)} \right)
  \]
Semi-supervised: Yarowsky algorithm

The task:

Learn a **decision list classifier** for each ambiguous word (e.g. “plant”: living/factory?) from lots of **unlabeled sentences**.

Features used by the classifier:

- **Collocations:** “plant life”, “manufacturing plant”
- **Nearby (± 2-10) words:** “animal”, “automate”

**Assumption 1:** **One-sense-per-collocation**

“plant” in “plant life” always refers to living plants

**Assumption 2:** **One-sense-per-discourse**

A text talks either about living plants or about factories.
Yarowsky’s training regime

1. **Initialization:**
   - Label a few seed examples.
   - Train an initial classifier on these seed examples

2. **Relabel:**
   - Label all examples with current classifier.
   - Put all examples that are labeled with high confidence into a new labeled data set.
   - Optional: apply one-sense-per-discourse to correct mistakes and get additional labels

3. **Retrain:**
   - Train a new classifier on the new labeled data set.

4. Repeat 2. and 3. until convergence.
Initial state: few labels

Figure 1: Sample Initial State

A = SENSE-A training example
B = SENSE-B training example
? = currently unclassified training example
Life = Set of training examples containing the collocation "life".
The initial decision list

</table>

...
Summary: Yarowsky algorithm

Semi-supervised approach for WSD.

Basic idea:
- start with some minimal seed knowledge to get a few labeled examples as training data
- train a classifier
- apply this classifier to new examples
- add the most confidently classified examples to the training data
- use heuristics (one-sense-per-discourse) to add even more labeled examples to the training data
- retrain the classifier, ….
Today’s key concepts
