Lecture 2: Finite-state methods for morphology

Julia Hockenmaier
juliahmr@illinois.edu
3324 Siebel Center

HW 0

HW0 will come out later today
(check the syllabus.html page on the website)

We will assume Python 3.5.2 for our assignments
(you shouldn't have to load any additional modules or libraries besides the ones we provide)

You get 2 points for HW0
(HW1—HW4 have 10 points each)
1 point for uploading something to Compass
1 point for uploading a tar.gz file with the correct name and file structure

Compass and enrollment…

We won’t be able to grade more than 100 assignments (and HW0 is only worth 2 points)
- Lecture slides and the PDFs for the assignments will always be posted on the class website.
- You don't need to be on Compass to get access.
- Piazza is also available to everybody.
If you are planning to drop this class, please do so ASAP, so that others can take your spot.

If you just got into the class, it is likely to take 24 hours to get access to Compass.
DRES accommodations

If you need any disability related accommodations, talk to DRES (http://disability.illinois.edu, disability@illinois.edu, phone 333-4603)

If you are concerned you have a disability-related condition that is impacting your academic progress, there are academic screening appointments available on campus that can help diagnosis a previously undiagnosed disability by visiting the DRES website and selecting “Sign-Up for an Academic Screening” at the bottom of the page.”

Come and talk to me as well, especially once you have a letter of accommodation from DRES.
Do this early enough so that we can take your requirements into account for exams and assignments.

Today's lecture

What is the structure of words? (in English, Chinese, Arabic,…)
Morphology: the area of linguistics that deals with this.

How can we identify the structure of words?
We need to build a morphological analyzer (parser).
We will use finite-state transducers for this task.

Finite-State Automata and Regular Languages
(Review)

NB: No probabilities or machine learning yet.
We’re thinking about (symbolic) representations today.

Last lecture

The NLP pipeline:
Tokenization — POS tagging — Syntactic parsing — Semantic analysis — Coreference resolution

Why is NLP difficult?
Ambiguity
Coverage

Morphology: What is a word?
A Turkish word

uygarlaşıramadıklarımızdanmışsınızcasına
uygar _la_ş _tir_ _ama_ _dik_ _lar_ _imiz_ _dan_ _miş_ _siniz_ _casına

“as if you are among those whom we were not able to civilize
(=cause to become civilized)”

uygar: civilized
_la_ş: become
_tir: cause somebody to do something
_ama: not able
_dik: past participle
_lar: plural
_imiz: 1st person plural possessive (our)
_dan: among (ablative case)
_miş: past
_siniz: 2nd person plural (you)
_casına: as if (forms an adverb from a verb) K. Oflazer pc to J&M

Basic word classes
(parts of speech)

Content words (open-class):
Nouns: student, university, knowledge,...
Verbs: write, learn, teach,...
Adjectives: difficult, boring, hard, ....
Adverbs: easily, repeatedly,...

Function words (closed-class):
Prepositions: in, with, under,...
Conjunctions: and, or,...
Determiners: a, the, every,...

Words aren’t just defined by blanks

Problem 1: Compounding
“ice cream”, “website”, “web site”, “New York-based”

Problem 2: Other writing systems have no blanks

Chinese: 我开始写小说 = 我 开始 写 小说
            I start(ed) writing novel(s)

Problem 3: Clitics

English: “doesn’t”, “I’m”,
Italian: “dirglielo” = dir + gli(e) + lo
            tell + him + it

How many words are there?

Of course he wants to take the advanced course too.
He already took two beginners’ courses.

This is a bad question. Did I mean:

How many word tokens are there?
(16 to 19, depending on how we count punctuation)

How many word types are there?
(i.e. How many different words are there?
Again, this depends on how you count, but it’s usually much less than the number of tokens)
How many words are there?

Of course he wants to take the advanced course too. He already took two beginners’ courses.

The same (underlying) word can take different forms: course/courses, take/took

We distinguish concrete word forms (take, taking) from abstract lemmas or dictionary forms (take)

Different words may be spelled/pronounced the same: of course vs. advanced course two vs. too

How many different words are there?

Inflection creates different forms of the same word:
Verbs: to be, being, I am, you are, he is, I was.
Nouns: one book, two books

Derivation creates different words from the same lemma:
grace ⇒ disgrace ⇒ disgraceful ⇒ disgracefully

Compounding combines two words into a new word:
cream ⇒ ice cream ⇒ ice cream cone ⇒ ice cream cone bakery

Word formation is productive:
New words are subject to all of these processes:
Google ⇒ Googler, to google, to ungoogle, to misgoogle, googlification, ungooglification, googlified, Google Maps, Google Maps service,...

Inflectional morphology in English

Verbs:
Infinitive/present tense: walk, go
3rd person singular present tense (s-form): walks, goes
Simple past: walked, went
Past participle (ed-form): walked, gone
Present participle (ing-form): walking, going

Nouns:
Common nouns inflect for number:
singular (book) vs. plural (books)
Personal pronouns inflect for person, number, gender, case:
I saw him; he saw me; you saw her; we saw them; they saw us.

Derivational morphology

Nominalization:
V + -ation: computerization
V+ -er: killer
Adj + -ness: fuzziness

Negation:
un-: undo, unseen, ...

mis-: mistake,...

Adjectivization:
V+ -able: doable
N + -al: national
Morphemes: stems, affixes

- dis-grace-ful-ly
- prefix-stem-suffix-suffix

Many word forms consist of a stem plus a number of affixes (prefixes or suffixes)

- Infixes are inserted inside the stem.
- Circumfixes (German *gesehen*) surround the stem.

Morphemes: the smallest (meaningful/grammatical) parts of words.
- *Stems* (grace) are often free morphemes.
- Free morphemes can occur by themselves as words.
- *Affixes* (dis-, -ful, -ly) are usually bound morphemes.
- Bound morphemes have to combine with others to form words.

Morphemes and morphs

- There are many *irregular* word forms:
  - Plural nouns add -s to singular: book-books, but: box-boxes, fly-flyes, child-children
  - Past tense verbs add -ed to infinitive: walk-walked, but: like-likeed, leap-leapt

One morpheme (e.g. for plural nouns) can be realized as different surface forms (morphs):
- -s/-es/-ren

Allomorphs: two different realizations (-s/-es/-ren) of the same underlying morpheme (plural)

Morphological parsing

- disgracefully
- dis grace ful ly
- prefix stem suffix suffix
- NEG grace+N +ADJ +ADV

Morphological parsing and generation
Morphological generation

We cannot enumerate all possible English words, but we would like to capture the rules that define whether a string could be an English word or not.

That is, we want a procedure that can generate (or accept) possible English words...

-grace, graceful, gracefully
-disgrace, disgraceful, disgracefully,
-ungraceful, ungracefully,
-undisgraceful, undisgracefully,... without generating/accepting impossible English words

*gracelyful, *gracefuly, *disungracefully,...

NB: * is linguists' shorthand for "this is ungrammatical"

Formal languages

An alphabet $\Sigma$ is a set of symbols:

e.g. $\Sigma = \{a, b, c\}$

A string $\omega$ is a sequence of symbols, e.g $\omega = abcb$. The empty string $\varepsilon$ consists of zero symbols.

The Kleene closure $\Sigma^*$ ("sigma star") is the (infinite) set of all strings that can be formed from $\Sigma$:

$\Sigma^* = \{\varepsilon, a, b, c, aa, ab, ba, aaa, \ldots\}$

A language $L \subseteq \Sigma^*$ over $\Sigma$ is also a set of strings. Typically we only care about proper subsets of $\Sigma^*$ ($L \subset \Sigma$).
An automaton is an abstract model of a computer. It reads an input string symbol by symbol. It changes its internal state depending on the current input symbol and its current internal state.

The automaton either accepts or rejects the input string. Every automaton defines a language (the set of strings it accepts).

Different types of automata define different language classes:

- **Finite-state** automata define regular languages
- **Pushdown** automata define context-free languages
- **Turing machines** define recursively enumerable languages

The Chomsky Hierarchy

The structure of English words can be described by a regular (= finite-state) grammar.
Finite-state automata

A (deterministic) finite-state automaton (FSA) consists of:

- a **finite set of states** \( Q = \{q_0, \ldots, q_N\} \), including a **start state** \( q_0 \) and one (or more) **final (accepting) states** (say, \( q_N \))
- a **(deterministic) transition function** \( \delta(q,w) = q' \) for \( q, q' \in Q, w \in \Sigma \)

```
move from state q2 to state q4 if you read 'y'
```

```
final state (note the double line)
```

```
start state
```

```
Rejection: Automaton does not end up in accepting state
```

```
Rejection: Transition not defined
```

CS447: Natural Language Processing (J. Hockemaier)
Finite State Automata (FSAs)

A finite-state automaton \( M = (Q, \Sigma, q_0, F, \delta) \) consists of:
- A finite set of states \( Q = \{q_0, q_1, ..., q_n\} \)
- A finite alphabet \( \Sigma \) of input symbols (e.g., \( \Sigma = \{a, b, c, \ldots\} \))
- A designated start state \( q_0 \in Q \)
- A set of final states \( F \subseteq Q \)
- A transition function \( \delta \):
  - The transition function for a deterministic (D)FSA: \( Q \times \Sigma \rightarrow Q \)
    \[ \delta(q, w) = q' \] for \( q, q' \in Q, w \in \Sigma \)
    If the current state is \( q \) and the current input is \( w \), go to \( q' \)
  - The transition function for a nondeterministic (N)FSA: \( Q \times \Sigma \rightarrow 2^Q \)
    \[ \delta(q, w) = Q' \] for \( q \in Q, Q' \subseteq Q, w \in \Sigma \)
    If the current state is \( q \) and the current input is \( w \), go to any \( q' \in Q' \)

Regular Expressions

Regular expressions can also be used to define a regular language.

Simple patterns:
- **Standard characters** match themselves: ‘a’, ‘l’
- **Character classes**: [abc], [0-9], negation: [^aeiou]
  (Predefined: \`s (whitespace), \`w (alphanumeric), etc.)
- **Any character** (except newline) is matched by ‘.’

Complex patterns: (e.g. ^[A-Z]([a-z]+\s)
- **Group**: ‘(...)’
- **Repetition**: 0 or more times: ‘*’, 1 or more times: ‘+’
- **Disjunction**: ‘|...
- **Beginning of line** ‘^’ and **end of line** ‘$’

Finite-state methods for morphology
**Finite state automata for morphology**

**grace:**

```
q0 → stem → q1
```

**dis-grace:**

```
q0 → prefix → q1 → stem → q2
```

**grace-ful:**

```
q0 → stem → suffix → q2
```

**dis-grace-ful:**

```
q0 → prefix → stem → suffix → q3
```

---

**Stem changes**

Some irregular words require stem changes:

- **Past tense verbs:**
  - teach → taught
  - go → went
  - write → wrote

- **Plural nouns:**
  - mouse → mice
  - foot → feet
  - wife → wives

---

**Union: merging automata**

```
q0 → prefix → ε → stem → suffix → q3
```

**grace,**

- dis-grace,

**grace-ful,**

- dis-grace-ful

---

**FSAs for derivational morphology**

```
q0 → reg-noun → q1 → plural-s → q2
```

- **noun1** = {fossil, mineral,...}
- **adj1** = {equal, neutral}
- **adj2** = {minim, maxim}
- **noun2** = {nation, form,...}
- **noun3** = {nature, structur,...}
Recognition vs. Analysis

FSAs can recognize (accept) a string, but they don’t tell us its internal structure.

We need is a machine that maps (transduces) the input string into an output string that encodes its structure:

\[
\begin{array}{c}
\text{Input} \\
\text{(Surface form)}
\end{array}
\begin{array}{c}
c a t s
\end{array}
\begin{array}{c}
\downarrow
\end{array}
\begin{array}{c}
\text{Output} \\
\text{(Lexical form)}
\end{array}
\begin{array}{c}
c a t +N+pl
\end{array}
\]

Finite-state transducers

A finite-state transducer \( T = (Q, \Sigma, \Delta, q_0, F, \delta, \sigma) \) consists of:
- A finite set of states \( Q = \{q_0, q_1, \ldots, q_n\} \)
- A finite alphabet \( \Sigma \) of input symbols (e.g. \( \Sigma = \{a, b, c, \ldots\} \))
- A finite alphabet \( \Delta \) of output symbols (e.g. \( \Delta = \{+N, +pl, \ldots\} \))
- A designated start state \( q_0 \in Q \)
- A set of final states \( F \subseteq Q \)
- A transition function \( \delta: Q \times \Sigma \rightarrow 2^Q \)
  \[ \delta(q,w) = Q' \text{ for } q \in Q, Q' \subseteq Q, w \in \Sigma \]
- An output function \( \sigma: Q \times \Sigma \rightarrow \Delta^* \)
  \[ \sigma(q,w) = \omega \text{ for } q \in Q, w \in \Sigma, \omega \in \Delta^* \]
If the current state is \( q \) and the current input is \( w \), write \( \omega \).
(NB: Jurafsky&Martin define \( \sigma: Q \times \Sigma^* \rightarrow \Delta^* \). Why is this equivalent?)

Finite-state transducers

An FST \( T = L_{in} \times L_{out} \) defines a relation between two regular languages \( L_{in} \) and \( L_{out} \):

\[
L_{in} = \{\text{cat, cats, fox, foxes, ...}\} \\
L_{out} = \{\text{cat+N+sg, cat+N+pl, fox+N+sg, fox+N+pl ...}\}
\]

\[
T = \{ \langle \text{cat}, \text{cat+N+sg} \rangle, \langle \text{cats}, \text{cat+N+pl} \rangle, \langle \text{fox}, \text{fox+N+sg} \rangle, \langle \text{foxes}, \text{fox+N+pl} \rangle \}
\]

Some FST operations

Inversion \( T^{-1} \):

The inversion \( (T^{-1}) \) of a transducer switches input and output labels.

\[ \text{This can be used to switch from parsing words to generating words.} \]

Composition \( (T \circ T') \): (Cascade)

Two transducers \( T = L_1 \times L_2 \) and \( T' = L_2 \times L_3 \) can be composed into a third transducer \( T'' = L_1 \times L_3 \).

\[ \text{Sometimes intermediate representations are useful} \]
English spelling rules

Peculiarities of English spelling (orthography)

The same underlying morpheme (e.g. plural-s) can have different orthographic “surface realizations” (-s, -es)

This leads to spelling changes at morpheme boundaries:
- E-insertion:  fox +s = foxes
- E-deletion:  make +ing = making

Intermediate representations

English plural -s: cat ⇒ cats  dog ⇒ dogs
but: fox ⇒ foxes,  bus ⇒ buses  buzz ⇒ buzzes

We define an intermediate representation to capture morpheme boundaries (^) and word boundaries (#):

Lexicon:  cat+N+PL  fox+N+PL
⇒ Intermediate representation:  cat^s#  fox^s#
⇒ Surface string:  cats  foxes

Intermediate-to-Surface Spelling Rule:
If plural ‘s’ follows a morpheme ending in ‘x’, ‘z’ or ‘s’, insert ‘e’.

Side note: “Surface realization”? 

This terminology comes from Chomskyan Transformational Grammar.
Dominant early approach in theoretical linguistics, superseded by other approaches (“minimalism”).
Not computational, but has some historical influence on computational linguistics (e.g. Penn Treebank)

“Surface” = standard English (Chinese, Hindi, etc.).
“Surface string” = a written sequence of characters or words
vs. “Deep”/“Underlying” structure/representation:
A more abstract representation.
Might be the same for different sentences with the same meaning.

FST composition/cascade: 

Lexical

Intermediate

Surface
Dealing with ambiguity

*book*: *book* +N +sg or *book* +V?
Generating words is generally unambiguous, but analyzing words often requires disambiguation.

We need a nondeterministic FST.
- Efficiency problem: Not every nondeterministic FST can be translated into a deterministic one!

We also need a scoring function to identify which analysis is more likely.
- We may need to know the context in which the word appears: (I read a book vs. I book flights)

Other applications of FSTs
A computer therapist?

**Computer:** TELL ME MORE ABOUT YOUR FAMILY
**Human:** My mother takes care of me.
**Computer:** WHO ELSE IN YOUR FAMILY TAKES CARE OF YOU
**Human:** My father.
**Computer:** YOUR FATHER
**Human:** You are like my father in some ways.
**Computer:** WHAT RESEMBLANCE DO YOU SEE
**Human:** You are not very aggressive but I think you don't want me to notice that.
**Computer:** WHAT MAKES YOU THINK I AM NOT VERY AGGRESSIVE
**Human:** You don't argue with me.
**Computer:** WHY DO YOU THINK I DON'T ARGUE WITH YOU
**Human:** You are afraid of me.

*Weizenbaum (1966), ELIZA.*

---

ELIZA as a FST cascade

**Human:** You don't argue with me.
**Computer:** WHY DO YOU THINK I DON'T ARGUE WITH YOU

1. Replace you with I and me with you:
   i don't argue with you.
2. Replace <...> with Why do you think <...>:
   Why do you think I don't argue with you.

What about other NLP tasks?

Could we write an FST for machine translation?

---

What about compounds?

Semantically, compounds have hierarchical structure:

- (((ice cream) cone) bakery)
- not (ice ((cream cone) bakery))

- (((computer science) (graduate student)))
- not (computer ((science graduate) student))

We will need context-free grammars to capture this underlying structure.

---

Today’s key concepts

Morphology (word structure): stems, affixes
Derivational vs. inflectional morphology
Compounding
Stem changes
Morphological analysis and generation

Finite-state automata
Finite-state transducers
Composing finite-state transducers
Today’s reading
