

# Reductions, Recursion and Divide and Conquer

Lecture 5

September 13, 2011

## Part I

### Reductions and Recursion

# Reduction

Reducing problem **A** to problem **B**:

- Algorithm for **A** uses algorithm for **B** as a *black box*

## Distinct Elements Problem

**Problem** Given an array **A** of  $n$  integers, are there any *duplicates* in **A**?

Naive algorithm:

```
for  $i = 1$  to  $n - 1$  do
  for  $j = i + 1$  to  $n$  do
    if ( $A[i] = A[j]$ )
      return YES
return NO
```

Running time:  $O(n^2)$

# Reduction to Sorting

```
Sort A
for  $i = 1$  to  $n - 1$  do
    if ( $A[i] = A[i + 1]$ ) then
        return YES
return NO
```

Running time:  $O(n)$  plus time to sort an array of  $n$  numbers

Important point: algorithm uses sorting as a black box

## Two sides of Reductions

Suppose problem **A** reduces to problem **B**

- **Positive direction:** Algorithm for **B** implies an algorithm for **A**
- **Negative direction:** Suppose there is no “efficient” algorithm for **A** then it implies no efficient algorithm for **B** (technical condition for reduction time necessary for this)

Example: Distinct Elements reduces to Sorting in  $O(n)$  time

- An  $O(n \log n)$  time algorithm for Sorting implies an  $O(n \log n)$  time algorithm for Distinct Elements problem.
- If there is *no*  $o(n \log n)$  time algorithm for Distinct Elements problem then there is *no*  $o(n \log n)$  time algorithm for Sorting.

Reduction: reduce one problem to another

Recursion: a special case of reduction

- reduce problem to a *smaller* instance of *itself*
- self-reduction
- Problem instance of size  $n$  is reduced to one or more instances of size  $n - 1$  or less.
- For termination, problem instances of small size are solved by some other method as *base cases*

# Recursion

- Recursion is a very powerful and fundamental technique
- Basis for several other methods
  - Divide and conquer
  - Dynamic programming
  - Enumeration and branch and bound etc
  - Some classes of greedy algorithms
- Makes proof of correctness easy (via induction)
- Recurrences arise in analysis

# Selection Sort

Sort a given array  $A[1..n]$  of integers.

Recursive version of Selection sort.

**SelectSort**( $A[1..n]$ ):

**if**  $n = 1$  **return**

  Find smallest number in  $A$ . Let  $A[j]$  be smallest number

  Swap  $A[1]$  and  $A[j]$

**SelectSort**( $A[2..n]$ )

$T(n)$ : time for **SelectSort** on an  $n$  element array.

$T(n) = T(n - 1) + n$  for  $n > 1$  and  $T(1) = 1$  for  $n = 1$

$T(n) = \Theta(n^2)$ .

# Tower of Hanoi

The Tower of Hanoi puzzle

Move stack of  $n$  disks from peg **0** to peg **2**, one disk at a time.

**Rule:** cannot put a larger disk on a smaller disk.

**Question:** what is a strategy and how many moves does it take?

# Tower of Hanoi via Recursion

The Tower of Hanoi algorithm; ignore everything but the bottom disk

## Recursive Algorithm

```
Hanoi( $n$ , src, dest, tmp):  
  if ( $n > 0$ ) then  
    Hanoi( $n - 1$ , src, tmp, dest)  
    Move disk  $n$  from src to dest  
    Hanoi( $n - 1$ , tmp, dest, src)
```

$T(n)$ : time to move  $n$  disks via recursive strategy

$$T(n) = 2T(n - 1) + 1 \quad n > 1 \quad \text{and} \quad T(1) = 1$$

$$\begin{aligned}T(n) &= 2T(n-1) + 1 \\&= 2^2T(n-2) + 2 + 1 \\&= \dots \\&= 2^i T(n-i) + 2^{i-1} + 2^{i-2} + \dots + 1 \\&= \dots \\&= 2^{n-1} T(1) + 2^{n-2} + \dots + 1 \\&= 2^{n-1} + 2^{n-2} + \dots + 1 \\&= (2^n - 1)/(2 - 1) = 2^n - 1\end{aligned}$$

## Non-Recursive Algorithms for Tower of Hanoi

Pegs numbered **0, 1, 2**

Non-recursive Algorithm 1:

- Always move smallest disk forward if  $n$  is even, backward if  $n$  is odd.
- Never move the same disk twice in a row.
- Done when no legal move.

Non-recursive Algorithm 2:

- Let  $\rho(n)$  be the smallest integer  $k$  such that  $n/2^k$  is *not* an integer. Example:  $\rho(40) = 4$ ,  $\rho(18) = 2$ .
- In step  $i$  move disk  $\rho(i)$  forward if  $n - i$  is even and backward if  $n - i$  is odd.

Moves are exactly same as those of recursive algorithm. Prove by induction.

# Part II

## Divide and Conquer

## Divide and Conquer Paradigm

Divide and Conquer is a common and useful type of recursion

### Approach

- Break problem instance into smaller instances - divide step
- **Recursively** solve problem on smaller instances
- Combine solutions to smaller instances to obtain a solution to the original instance - conquer step

**Question:** Why is this not plain recursion?

- In divide and conquer, each smaller instance is typically at least a constant factor smaller than the original instance which leads to efficient running times.
- There are many examples of this particular type of recursion that it deserves its own treatment.

**Input** Given an array of  $n$  elements

**Goal** Rearrange them in ascending order

## Merge Sort [von Neumann]

### MergeSort

- 1 **Input:** Array  $A[1 \dots n]$

*A L G O R I T H M S*

- 2 Divide into subarrays  $A[1 \dots m]$  and  $A[m + 1 \dots n]$ , where  $m = \lfloor n/2 \rfloor$

*A L G O R I T H M S*

- 3 Recursively **MergeSort**  $A[1 \dots m]$  and  $A[m + 1 \dots n]$

*A G L O R H I M S T*

- 4 **Merge** the sorted arrays

*A G H I L M O R S T*

# Merging Sorted Arrays

- Use a new array  $C$  to store the merged array
- Scan  $A$  and  $B$  from left-to-right, storing elements in  $C$  in order

**A G L O R   H I M S T**  
**A G H I L M O R S T**

- Merge two arrays using only constantly more extra space (in-place merge sort): doable but complicated and typically impractical

## Running Time

$T(n)$ : time for merge sort to sort an  $n$  element array

$$T(n) = T(\lfloor n/2 \rfloor) + T(\lceil n/2 \rceil) + cn$$

What do we want as a solution to the recurrence?

Almost always only an *asymptotically* tight bound. That is we want to know  $f(n)$  such that  $T(n) = \Theta(f(n))$ .

- $T(n) = O(f(n))$  - upper bound
- $T(n) = \Omega(f(n))$  - lower bound

# Solving Recurrences: Some Techniques

- Know some basic math: geometric series, logarithms, exponentials, elementary calculus
- Expand the recurrence and spot a pattern and use simple math
- **Recursion tree method** — imagine the computation as a tree
- **Guess and verify** — useful for proving upper and lower bounds even if not tight bounds

**Albert Einstein:** “Everything should be made as simple as possible, but not simpler.”

Know where to be loose in analysis and where to be tight. Comes with practice, practice, practice!

## Recursion Trees

MergeSort: **n** is a power of 2

- Unroll the recurrence.  $T(n) = 2T(n/2) + cn$

- Identify a pattern. At the  $i$ th level total work is  $cn$
- Sum over all levels. The number of levels is  $\log n$ . So total is  $cn \log n = O(n \log n)$

# Recursion Trees

An illustrated example...

## MergeSort Analysis

When  $n$  is not a power of 2

- When  $n$  is not a power of 2, the running time of **MergeSort** is expressed as

$$T(n) = T(\lfloor n/2 \rfloor) + T(\lceil n/2 \rceil) + cn$$

- $n_1 = 2^{k-1} < n \leq 2^k = n_2$  ( $n_1, n_2$  powers of 2)
- $T(n_1) < T(n) \leq T(n_2)$  (Why?)
- $T(n) = \Theta(n \log n)$  since  $n/2 \leq n_1 < n \leq n_2 \leq 2n$ .

**MergeSort:**  $n$  is not a power of 2

$$T(n) = T(\lfloor n/2 \rfloor) + T(\lceil n/2 \rceil) + cn$$

**Observation:** For any number  $x$ ,  $\lfloor x/2 \rfloor + \lceil x/2 \rceil = x$ .

# MergeSort Analysis

When  $n$  is not a power of 2: Guess and Verify

If  $n$  is power of 2 we saw that  $T(n) = \Theta(n \log n)$ .

Can guess that  $T(n) = \Theta(n \log n)$  for all  $n$ .

Verify? proof by induction!

**Induction Hypothesis:**  $T(n) \leq 2cn \log n$  for all  $n \geq 1$

**Base Case:**  $n = 1$ .  $T(1) = 0$  since no need to do any work and  $2cn \log n = 0$  for  $n = 1$ .

**Induction Step** Assume  $T(k) \leq 2ck \log k$  for all  $k < n$  and prove it for  $k = n$ .

## Induction Step

We have

$$\begin{aligned} T(n) &= T(\lfloor n/2 \rfloor) + T(\lceil n/2 \rceil) + cn \\ &\leq 2c\lfloor n/2 \rfloor \log \lfloor n/2 \rfloor + 2c\lceil n/2 \rceil \log \lceil n/2 \rceil + cn \quad (\text{by induction}) \\ &\leq 2c\lfloor n/2 \rfloor \log \lceil n/2 \rceil + 2c\lceil n/2 \rceil \log \lceil n/2 \rceil + cn \\ &\leq 2c(\lfloor n/2 \rfloor + \lceil n/2 \rceil) \log \lceil n/2 \rceil + cn \\ &\leq 2cn \log \lceil n/2 \rceil + cn \\ &\leq 2cn \log(2n/3) + cn \quad (\text{since } \lceil n/2 \rceil \leq 2n/3 \text{ for all } n \geq 2) \\ &\leq 2cn \log n + cn(1 - 2 \log 3/2) \\ &\leq 2cn \log n + cn(\log 2 - \log 9/4) \\ &\leq 2cn \log n \end{aligned}$$

# Guess and Verify

The math worked out like magic!

Why was  $2cn \log n$  chosen instead of say  $4cn \log n$ ?

- Do not know upfront what constant to choose.
- Instead assume that  $T(n) \leq \alpha cn \log n$  for some constant  $\alpha$ .  $\alpha$  will be fixed later.
- Need to prove that for  $\alpha$  large enough the algebra goes through.
- In our case... need  $\alpha$  such that  $\alpha \log 3/2 > 1$ .
- Typically, do the algebra with  $\alpha$  and then show that it works...  
... if  $\alpha$  is chosen to be sufficiently large constant.

# Guess and Verify

What happens if the guess is wrong?

- Gessed that the solution to the **MergeSort** recurrence is  $T(n) = O(n)$ .
- Try to prove by induction that  $T(n) \leq \alpha cn$  for some constant  $\alpha$ .  
**Induction Step:** attempt

$$\begin{aligned} T(n) &= T(\lfloor n/2 \rfloor) + T(\lceil n/2 \rceil) + cn \\ &\leq \alpha c \lfloor n/2 \rfloor + \alpha c \lceil n/2 \rceil + cn \\ &\leq \alpha cn + cn \\ &\leq (\alpha + 1)cn \end{aligned}$$

But need to show that  $T(n) \leq \alpha cn$ !

- So guess does not work for **any** constant  $\alpha$ . Suggest that our guess is incorrect.

# Selection Sort vs Merge Sort

- Selection Sort spends  $O(n)$  work to reduce problem from  $n$  to  $n - 1$  leading to  $O(n^2)$  running time.
- Merge Sort spends  $O(n)$  time *after* reducing problem to two instances of size  $n/2$  each. Running time is  $O(n \log n)$

**Question:** Merge Sort splits into 2 (roughly) equal sized arrays. Can we do better by splitting into more than 2 arrays? Say  $k$  arrays of size  $n/k$  each?

## Quick Sort

### Quick Sort [Hoare]

- 1 Pick a pivot element from array
- 2 Split array into 3 subarrays: those smaller than pivot, those larger than pivot, and the pivot itself. Linear scan of array does it. Time is  $O(n)$
- 3 Recursively sort the subarrays, and concatenate them.

Example:

- array: 16, 12, 14, 20, 5, 3, 18, 19, 1
- pivot: 16
- split into 12, 14, 5, 3, 1 and 20, 19, 18 and recursively sort
- put them together with pivot in middle

- Let  $k$  be the rank of the chosen pivot. Then,  
 $T(n) = T(k - 1) + T(n - k) + O(n)$
- If  $k = \lceil n/2 \rceil$  then  
 $T(n) = T(\lceil n/2 \rceil - 1) + T(\lfloor n/2 \rfloor) + O(n) \leq 2T(n/2) + O(n)$ .  
Then,  $T(n) = O(n \log n)$ .
  - Theoretically, median can be found in linear time.
- Typically, pivot is the first or last element of array. Then,

$$T(n) = \max_{1 \leq k \leq n} (T(k - 1) + T(n - k) + O(n))$$

In the worst case  $T(n) = T(n - 1) + O(n)$ , which means  $T(n) = O(n^2)$ . Happens if array is already sorted and pivot is always first element.

## Part III

### Fast Multiplication

# Multiplying Numbers

**Problem** Given two  $n$ -digit numbers  $x$  and  $y$ , compute their product.

## Grade School Multiplication

Compute “partial product” by multiplying each digit of  $y$  with  $x$  and adding the partial products.

$$\begin{array}{r} 3141 \\ \times 2718 \\ \hline 25128 \\ 3141 \\ 21987 \\ 6282 \\ \hline 8537238 \end{array}$$

## Time Analysis of Grade School Multiplication

- Each partial product:  $\Theta(n)$
- Number of partial products:  $\Theta(n)$
- Addition of partial products:  $\Theta(n^2)$
- Total time:  $\Theta(n^2)$

# A Trick of Gauss

Carl Fridrich Gauss: 1777–1855 “Prince of Mathematicians”

Observation: Multiply two complex numbers:  $(a + bi)$  and  $(c + di)$

$$(a + bi)(c + di) = ac - bd + (ad + bc)i$$

How many multiplications do we need?

Only 3! If we do extra additions and subtractions.

Compute  $ac$ ,  $bd$ ,  $(a + b)(c + d)$ . Then

$$(ad + bc) = (a + b)(c + d) - ac - bd$$

## Divide and Conquer

Assume  $n$  is a power of 2 for simplicity and numbers are in decimal.

- $x = x_{n-1}x_{n-2} \dots x_0$  and  $y = y_{n-1}y_{n-2} \dots y_0$
- $x = 10^{n/2}x_L + x_R$  where  $x_L = x_{n-1} \dots x_{n/2}$  and  $x_R = x_{n/2-1} \dots x_0$
- $y = 10^{n/2}y_L + y_R$  where  $y_L = y_{n-1} \dots y_{n/2}$  and  $y_R = y_{n/2-1} \dots y_0$

Therefore

$$\begin{aligned} xy &= (10^{n/2}x_L + x_R)(10^{n/2}y_L + y_R) \\ &= 10^n x_L y_L + 10^{n/2}(x_L y_R + x_R y_L) + x_R y_R \end{aligned}$$

# Example

$$\begin{aligned}1234 \times 5678 &= (100 \times 12 + 34) \times (100 \times 56 + 78) \\ &= 10000 \times 12 \times 56 \\ &\quad + 100 \times (12 \times 78 + 34 \times 56) \\ &\quad + 34 \times 78\end{aligned}$$

## Time Analysis

$$\begin{aligned}xy &= (10^{n/2}x_L + x_R)(10^{n/2}y_L + y_R) \\ &= 10^n x_L y_L + 10^{n/2}(x_L y_R + x_R y_L) + x_R y_R\end{aligned}$$

4 recursive multiplications of number of size  $n/2$  each plus 4 additions and left shifts (adding enough 0's to the right)

$$T(n) = 4T(n/2) + O(n) \quad T(1) = O(1)$$

$T(n) = \Theta(n^2)$ . No better than grade school multiplication!

Can we invoke Gauss's trick here?

# Improving the Running Time

$$\begin{aligned}xy &= (10^{n/2}x_L + x_R)(10^{n/2}y_L + y_R) \\ &= 10^n x_L y_L + 10^{n/2}(x_L y_R + x_R y_L) + x_R y_R\end{aligned}$$

Gauss trick:  $x_L y_R + x_R y_L = (x_L + x_R)(y_L + y_R) - x_L y_L - x_R y_R$

Recursively compute only  $x_L y_L$ ,  $x_R y_R$ ,  $(x_L + x_R)(y_L + y_R)$ .

## Time Analysis

Running time is given by

$$T(n) = 3T(n/2) + O(n) \qquad T(1) = O(1)$$

which means  $T(n) = O(n^{\log_2 3}) = O(n^{1.585})$

## State of the Art

Schönhage-Strassen 1971:  $O(n \log n \log \log n)$  time using Fast-Fourier-Transform (FFT)

Martin Fürer 2007:  $O(n \log n 2^{O(\log^* n)})$  time

## Conjecture

There is an  $O(n \log n)$  time algorithm.

# Analyzing the Recurrences

- Basic divide and conquer:  $T(n) = 4T(n/2) + O(n)$ ,  $T(1) = 1$ . **Claim:**  $T(n) = \Theta(n^2)$ .
- Saving a multiplication:  $T(n) = 3T(n/2) + O(n)$ ,  $T(1) = 1$ . **Claim:**  $T(n) = \Theta(n^{1+\log 1.5})$

Use recursion tree method:

- In both cases, depth of recursion  $L = \log n$ .
- Work at depth  $i$  is  $4^i n / 2^i$  and  $3^i n / 2^i$  respectively: number of children at depth  $i$  times the work at each child
- Total work is therefore  $n \sum_{i=0}^L 2^i$  and  $n \sum_{i=0}^L (3/2)^i$  respectively.

## Recursion tree analysis
