Chapter 12

Greedy Algorithms for Minimum Spanning Trees

CS 473: Fundamental Algorithms, Spring 2013
March 1, 2013

12.1 Greedy Algorithms: Minimum Spanning Tree

12.2 Minimum Spanning Tree

12.2.1 The Problem

Input  Connected graph $G = (V, E)$ with edge costs

Goal  Find $T \subseteq E$ such that $(V, T)$ is connected and total cost of all edges in $T$ is smallest

(A) $T$ is the minimum spanning tree (MST) of $G$
12.2.1.2 Applications

(A) Network Design
   (A) Designing networks with minimum cost but maximum connectivity
(B) Approximation algorithms
   (A) Can be used to bound the optimality of algorithms to approximate Traveling Sales-
   man Problem, Steiner Trees, etc.
(C) Cluster Analysis

12.2.2 The Algorithms

12.2.2.1 Greedy Template

Initially $E$ is the set of all edges in $G$
$T$ is empty (* T will store edges of a MST *)
while $E$ is not empty do
   choose $i \in E$
   if ($i$ satisfies condition)
      add $i$ to $T$
return the set $T$

Main Task: In what order should edges be processed? When should we add edge to spanning tree?

12.2.2.2 Kruskal’s Algorithm

Process edges in the order of their costs (starting from the least) and add edges to $T$ as long as they don’t form a cycle.
MST of $G$: 

$$
\begin{array}{c}
\text{1} \\
\text{6} \\
\text{5} \\
\text{7} \\
\text{3} \\
\text{2} \\
\text{4} \\
\end{array}
$$

$$
\begin{array}{c}
\text{1} \\
\text{6} \\
\text{5} \\
\text{7} \\
\text{3} \\
\text{2} \\
\text{4} \\
\end{array}
$$

$$
\begin{array}{c}
\text{1} \\
\text{6} \\
\text{5} \\
\text{7} \\
\text{3} \\
\text{2} \\
\text{4} \\
\end{array}
$$

$$
\begin{array}{c}
\text{1} \\
\text{6} \\
\text{5} \\
\text{7} \\
\text{3} \\
\text{2} \\
\text{4} \\
\end{array}
$$

$$
\begin{array}{c}
\text{1} \\
\text{6} \\
\text{5} \\
\text{7} \\
\text{3} \\
\text{2} \\
\text{4} \\
\end{array}
$$

$$
\begin{array}{c}
\text{1} \\

\text{5} \\
\text{7} \\
\text{3} \\
\text{2} \\
\text{4} \\
\end{array}
$$
12.2.2.3 Prim’s Algorithm

$T$ maintained by algorithm will be a tree. Start with a node in $T$. In each iteration, pick edge with least attachment cost to $T$. 
Order of edges considered:
12.2.4 Reverse Delete Algorithm

Initially $E$ is the set of all edges in $G$

$T$ is $E$ (∗ $T$ will store edges of a MST ∗)

while $E$ is not empty do

choose $i \in E$ of largest cost

if removing $i$ does not disconnect $T$ then

remove $i$ from $T$

end if

end while

return the set $T$

Returns a minimum spanning tree.

12.2.3 Correctness
12.2.3.1 Correctness of MST Algorithms

(A) Many different MST algorithms

(B) All of them rely on some basic properties of MSTs, in particular the Cut Property to be seen shortly.

12.2.4 Assumption
12.2.4.1 And for now . . .

Assumption 12.2.1. Edge costs are distinct, that is no two edge costs are equal.

12.2.4.2 Cuts

Definition 12.2.2. Given a graph $G = (V, E)$, a cut is a partition of the vertices of the graph into two sets $(S, V \setminus S)$.

Edges having an endpoint on both sides are the edges of the cut.

A cut edge is crossing the cut.

\[ \text{S} \quad \text{V} \setminus \text{S} \]

\[ \text{S} \quad \text{V} \setminus \text{S} \]
12.2.4.3 Safe and Unsafe Edges

**Definition 12.2.3.** An edge \( e = (u, v) \) is a **safe** edge if there is some partition of \( V \) into \( S \) and \( V \setminus S \) and \( e \) is the unique minimum cost edge crossing \( S \) (one end in \( S \) and the other in \( V \setminus S \)).

**Definition 12.2.4.** An edge \( e = (u, v) \) is an **unsafe** edge if there is some cycle \( C \) such that \( e \) is the unique maximum cost edge in \( C \).

**Proposition 12.2.5.** If edge costs are distinct then every edge is either safe or unsafe.

*Proof:* Exercise.

### 12.2.5 Safe edge

#### 12.2.5.1 Example...

Every cut identifies one safe edge...

![Safe edge in the cut \((S, V \setminus S)\)](image)

...the cheapest edge in the cut.

*Note:* An edge \( e \) may be a safe edge for *many* cuts!

### 12.2.6 Unsafe edge

#### 12.2.6.1 Example...

Every cycle identifies one **unsafe** edge...

![Unsafe edge in the cycle](image)

...the most expensive edge in the cycle.

#### 12.2.6.2 Example

And all safe edges are in the **MST** in this case...
Figure 12.1: Graph with unique edge costs. Safe edges are red, rest are unsafe.

12.2.6.3 Key Observation: Cut Property

Lemma 12.2.6. If $e$ is a safe edge then every minimum spanning tree contains $e$.

Proof:
(A) Suppose (for contradiction) $e$ is not in MST $T$.
(B) Since $e$ is safe there is an $S \subset V$ such that $e$ is the unique min cost edge crossing $S$.
(C) Since $T$ is connected, there must be some edge $f$ with one end in $S$ and the other in $V \setminus S$
(D) Since $c_f > c_e$, $T' = (T \setminus \{f\}) \cup \{e\}$ is a spanning tree of lower cost! **Error:** $T'$ may **not** be a spanning tree!!

12.2.7 Error in Proof: Example

12.2.7.1 Problematic example. $S = \{1, 2, 7\}$, $e = (7, 3)$, $f = (1, 6)$. $T - f + e$ is not a spanning tree.
(A) Consider adding the edge $f$.
(B) It is safe because it is the cheapest edge in the cut.
(C) Lets throw out the edge $e$ currently in the spanning tree which is more expensive than $f$ and is in the same cut. Put it $f$ instead...
(D) New graph of selected edges is not a tree anymore. BUG.

12.2.7.2 Proof of Cut Property

Proof:

(A) Suppose $e = (v, w)$ is not in MST $T$ and $e$ is min weight edge in cut $(S, V \setminus S)$. Assume $v \in S$.
(B) $T$ is spanning tree: there is a unique path $P$ from $v$ to $w$ in $T$
(C) Let $w'$ be the first vertex in $P$ belonging to $V \setminus S$; let $v'$ be the vertex just before it on $P$, and let $e' = (v', w')$
(D) $T' = (T \setminus \{e'\}) \cup \{e\}$ is spanning tree of lower cost. (Why?)
12.2.7.3  Proof of Cut Property (contd)

Observation 12.2.7.  \( T' = (T \setminus \{e'\}) \cup \{e\} \) is a spanning tree.

Proof:  \( T' \) is connected.

Removed \( e' = (v', w') \) from \( T \) but \( v' \) and \( w' \) are connected by the path \( P - f + e \) in \( T' \).

Hence \( T' \) is connected if \( T \) is.

\( T' \) is a tree

\( T' \) is connected and has \( n - 1 \) edges (since \( T \) had \( n - 1 \) edges) and hence \( T' \) is a tree.

12.2.7.4  Safe Edges form a Tree

Lemma 12.2.8.  Let \( G \) be a connected graph with distinct edge costs, then the set of safe edges form a connected graph.

Proof:

(A) Suppose not. Let \( S \) be a connected component in the graph induced by the safe edges.

(B) Consider the edges crossing \( S \), there must be a safe edge among them since edge costs are distinct and so we must have picked it.

12.2.7.5  Safe Edges form an MST

Corollary 12.2.9.  Let \( G \) be a connected graph with distinct edge costs, then set of safe edges form the unique MST of \( G \).

Consequence:  Every correct MST algorithm when \( G \) has unique edge costs includes exactly the safe edges.

12.2.7.6  Cycle Property

Lemma 12.2.10.  If \( e \) is an unsafe edge then no MST of \( G \) contains \( e \).

Proof:  Exercise. See textbook.

Note:  Cut and Cycle properties hold even when edge costs are not distinct. Safe and unsafe definitions do not rely on distinct cost assumption.
12.2.7.7 Correctness of Prim’s Algorithm

Prim’s Algorithm Pick edge with minimum attachment cost to current tree, and add to current tree.

Proof:[Proof of correctness]
(A) If e is added to tree, then e is safe and belongs to every MST.
   (A) Let S be the vertices connected by edges in T when e is added.
   (B) e is edge of lowest cost with one end in S and the other in V \ S and hence e is safe.
(B) Set of edges output is a spanning tree
   (A) Set of edges output forms a connected graph: by induction, S is connected in each iteration and eventually S = V.
   (B) Only safe edges added and they do not have a cycle

12.2.7.8 Correctness of Kruskal’s Algorithm

Kruskal’s Algorithm Pick edge of lowest cost and add if it does not form a cycle with existing edges.

Proof:[Proof of correctness]
(A) If e = (u, v) is added to tree, then e is safe
   (A) When algorithm adds e let S and S’ be the connected components containing u and v respectively
   (B) e is the lowest cost edge crossing S (and also S’).
   (C) If there is an edge e’ crossing S and has lower cost than e, then e’ would come before e in the sorted order and would be added by the algorithm to T
(B) Set of edges output is a spanning tree : exercise

12.2.7.9 Correctness of Reverse Delete Algorithm

Reverse Delete Algorithm Consider edges in decreasing cost and remove an edge if it does not disconnect the graph

Proof:[Proof of correctness] Argue that only unsafe edges are removed (see text book).

12.2.7.10 When edge costs are not distinct

Heuristic argument: Make edge costs distinct by adding a small tiny and different cost to each edge

Formal argument: Order edges lexicographically to break ties
(A) e_i < e_j if either c(e_i) < c(e_j) or (c(e_i) = c(e_j) and i < j)
(B) Lexicographic ordering extends to sets of edges. If A, B ⊆ E, A ≠ B then A < B if either c(A) < c(B) or (c(A) = c(B) and A \ B has a lower indexed edge than B \ A)
Can order all spanning trees according to lexicographic order of their edge sets. Hence there is a unique MST.

Prim’s, Kruskal, and Reverse Delete Algorithms are optimal with respect to lexicographic ordering.

12.2.7.11 Edge Costs: Positive and Negative

(A) Algorithms and proofs don’t assume that edge costs are non-negative! MST algorithms work for arbitrary edge costs.
(B) Another way to see this: make edge costs non-negative by adding to each edge a large enough positive number. Why does this work for MSTs but not for shortest paths?
(C) Can compute maximum weight spanning tree by negating edge costs and then computing an MST.

12.3 Data Structures for MST: Priority Queues and Union-Find

12.4 Data Structures

12.4.1 Implementing Prim’s Algorithm

12.4.2 Implementing Prim’s Algorithm

12.4.2.1 Implementing Prim’s Algorithm

```
Prim_ComputeMST
E is the set of all edges in G
S = {1}
T is empty ( * T will store edges of a MST *)
<2> while S ≠ V do
     <3> pick e = (v, w) ∈ E such that
         v ∈ S and w ∈ V - S
         e has minimum cost
     T = T ∪ e
     S = S ∪ w
 return the set T
```

Analysis

(A) Number of iterations = O(n), where n is number of vertices
(B) Picking e is O(m) where m is the number of edges
(C) Total time O(nm)
12.4.3 Implementing Prim’s Algorithm

12.4.3.1 More Efficient Implementation

```
Prim_ComputeMST
  E is the set of all edges in G
  S = {1}
  T is empty (∗ T will store edges of a MST ∗)
  for v ∉ S, a(v) = min_{w∈S} c(w, v)
  for v ∉ S, e(v) = w such that w ∈ S and c(w, v) is minimum
  while S ≠ V do
    pick v with minimum a(v)
    T = T ∪ {(e(v), v)}
    S = S ∪ {v}
    update arrays a and e
  return the set T
```

Maintain vertices in \( V \setminus S \) in a priority queue with key \( a(v) \).

12.4.4 Priority Queues

12.4.4.1 Priority Queues

Data structure to store a set \( S \) of \( n \) elements where each element \( v \in S \) has an associated real/integer key \( k(v) \) such that the following operations

(A) **makeQ**: create an empty queue
(B) **findMin**: find the minimum key in \( S \)
(C) **extractMin**: Remove \( v \in S \) with smallest key and return it
(D) **add\((v, k(v))\)**: Add new element \( v \) with key \( k(v) \) to \( S \)
(E) **Delete\((v)\)**: Remove element \( v \) from \( S \)
(F) **decreaseKey\((v, k'(v))\)**: decrease key of \( v \) from \( k(v) \) (current key) to \( k'(v) \) (new key).
   Assumption: \( k'(v) ≤ k(v) \)
(G) **meld**: merge two separate priority queues into one

12.4.4.2 Prim’s using priority queues

```
E is the set of all edges in G
S = {1}
T is empty (∗ T will store edges of a MST ∗)
for v ∉ S, a(v) = min_{w∈S} c(w, v)
for v ∉ S, e(v) = w such that w ∈ S and c(w, v) is minimum
while S ≠ V do
  pick v with minimum a(v)
  T = T ∪ {(e(v), v)}
  S = S ∪ {v}
  <3>update arrays a and e
  return the set T
```

Maintain vertices in \( V \setminus S \) in a priority queue with key \( a(v) \)
12.4.4.3 Running time of Prim’s Algorithm

\(O(n)\) extractMin operations and \(O(m)\) decreaseKey operations

(A) Requires \(O(n)\) extractMin operations
(B) Requires \(O(m)\) decreaseKey operations

Prim’s algorithm and Dijkstra’s algorithms are similar. Where is the difference?

12.4.5 Implementing Kruskal’s Algorithm

12.4.5.1 Kruskal’s Algorithm

\begin{algorithm}
\textbf{Kruskal ComputeMST}
\begin{algorithmic}
\STATE Initially \(E\) is the set of all edges in \(G\)
\STATE \(T\) is empty (\(\ast\) \(T\) will store edges of a MST \(\ast\))
\WHILE {\(E\) is not empty}
\STATE <2-3> choose \(e \in E\) of minimum cost
\STATE <4-5> if \((T \cup \{e\}\) does not have cycles)
\STATE add \(e\) to \(T\)
\ENDWHILE
\RETURN the set \(T\)
\end{algorithmic}
\end{algorithm}

(A) Presort edges based on cost. Choosing minimum can be done in \(O(1)\) time
(B) Do BFS/DFS on \(T \cup \{e\}\). Takes \(O(n)\) time
(C) Total time \(O(m \log m) + O(mn) = O(mn)\)

12.4.5.2 Implementing Kruskal’s Algorithm Efficiently

\begin{algorithm}
\textbf{Kruskal ComputeMST}
\begin{algorithmic}
\STATE Sort edges in \(E\) based on cost
\STATE \(T\) is empty (\(\ast\) \(T\) will store edges of a MST \(\ast\))
\STATE each vertex \(u\) is placed in a set by itself
\WHILE {\(E\) is not empty}
\STATE pick \(e = (u, v) \in E\) of minimum cost
\STATE <2-> if \(u\) and \(v\) belong to different sets
\STATE add \(e\) to \(T\)
\STATE <2-> merge the sets containing \(u\) and \(v\)
\ENDWHILE
\RETURN the set \(T\)
\end{algorithmic}
\end{algorithm}

Need a data structure to check if two elements belong to same set and to merge two sets.

12.4.6 Union-Find Data Structure

12.4.6.1 Union-Find Data Structure

Data Structure Store disjoint sets of elements that supports the following operations
(A) `makeUnionFind(S)` returns a data structure where each element of $S$ is in a separate set
(B) `find(u)` returns the name of set containing element $u$. Thus, $u$ and $v$ belong to the same set if and only if `find(u) = find(v)`
(C) `union(A, B)` merges two sets $A$ and $B$. Here $A$ and $B$ are the names of the sets. Typically the name of a set is some element in the set.

12.4.6.2 Implementing Union-Find using Arrays and Lists

Using lists
(A) Each set stored as list with a name associated with the list.
(B) For each element $u \in S$ a pointer to the its set. Array for pointers: `component[u]` is pointer for $u$.
(C) `makeUnionFind(S)` takes $O(n)$ time and space.

12.4.6.3 Example

```
12.4.6.4 Implementing Union-Find using Arrays and Lists

(A) `find(u)` reads the entry `component[u]`: $O(1)$ time
(B) `union(A, B)` involves updating the entries `component[u]` for all elements $u$ in $A$ and $B$: $O(|A| + |B|)$ which is $O(n)$
```
12.4.6.5 Improving the List Implementation for Union

New Implementation As before use component[u] to store set of u.
Change to union(A,B):
(A) with each set, keep track of its size
(B) assume |A| \leq |B| for now
(C) Merge the list of A into that of B: O(1) time (linked lists)
(D) Update component[u] only for elements in the smaller set A
(E) Total O(|A|) time. Worst case is still O(n).
find still takes O(1) time

12.4.6.6 Example

```
s t
u w y
v x
y
z

s t
u w y
v x
y
z
```
The smaller set (list) is appended to the largest set (list)

12.4.6.7 Improving the List Implementation for Union

Question Is the improved implementation provably better or is it simply a nice heuristic?

**Theorem 12.4.1.** Any sequence of k union operations, starting from makeUnionFind(S) on set S of size n, takes at most O(k log k).

**Corollary 12.4.2.** Kruskal’s algorithm can be implemented in O(m log m) time.

Sorting takes O(m log m) time, O(m) finds take O(m) time and O(n) unions take O(n log n) time.

12.4.6.8 Amortized Analysis

Why does theorem work?

Key Observation union(A,B) takes O(|A|) time where |A| \leq |B|. Size of new set is \geq 2|A|. Cannot double too many times.

12.4.6.9 Proof of Theorem

**Proof:**

(A) Any union operation involves at most 2 of the original one-element sets; thus at least 
\( n - 2k \) elements have never been involved in a union
Also, maximum size of any set (after \( k \) unions) is \( 2^k \).

\( \text{union}(A, B) \) takes \( O(|A|) \) time where \( |A| \leq |B| \).

\( \text{Charge} \) each element in \( A \) constant time to pay for \( O(|A|) \) time.

How much does any element get charged?

If \( \text{component} [v] \) is updated, set containing \( v \) doubles in size

\( \text{component} [v] \) is updated at most \( \log 2^k \) times

Total number of updates is \( 2^k \log 2^k = O(k \log k) \)

---

### 12.4.6.10 Improving Worst Case Time

Better data structure

Maintain elements in a forest of \( \text{in-trees} \); all elements in one tree belong to a set with root’s name.

\( \text{find}(u) \): Traverse from \( u \) to the root

\( \text{union}(A, B) \): Make root of \( A \) (smaller set) point to root of \( B \). Takes \( O(1) \) time.

### 12.4.6.11 Details of Implementation

Each element \( u \in S \) has a pointer \( \text{parent}(u) \) to its ancestor.

\[
\text{makeUnionFind}(S)
\]
for each \( u \) in \( S \) do
\[
\text{parent}(u) = u
\]

\[
\text{find}(u)
\]
while \( \text{parent}(u) \neq u \) do
\[
\text{u} = \text{parent}(u)
\]

return \( u \)

\[
\text{union}(\text{component}(u), \text{component}(v))
\]
\[
\text{if} \ (|\text{component}(u)| \leq |\text{component}(v)|) \text{ then}
\]
\[
\text{parent}(u) = v
\]

\[
\text{else}
\]
\[
\text{parent}(v) = u
\]

set new component size to \( |\text{component}(u)| + |\text{component}(v)| \)

### 12.4.6.12 Analysis

**Theorem 12.4.3.** The forest based implementation for a set of size \( n \), has the following complexity for the various operations: \( \text{makeUnionFind} \) takes \( O(n) \), \( \text{union} \) takes \( O(1) \), and \( \text{find} \) takes \( O(\log n) \).

**Proof:**

\( \text{find}(u) \) depends on the height of tree containing \( u \).

Height of \( u \) increases by at most 1 only when the set containing \( u \) changes its name.

If height of \( u \) increases then size of the set containing \( u \) (at least) doubles.

Maximum set size is \( n \); so height of any tree is at most \( O(\log n) \).
12.4.6.13 Further Improvements: Path Compression

Observation 12.4.4. Consecutive calls of $\text{find}(u)$ take $O(\log n)$ time each, but they traverse the same sequence of pointers.

Idea: Path Compression Make all nodes encountered in the $\text{find}(u)$ point to root.

12.4.6.14 Path Compression: Example

12.4.6.15 Path Compression

```
find(u):
    if (parent(u) ≠ u) then
        parent(u) = find(parent(u))
    return parent(u)
```

Question Does Path Compression help?
Yes!

Theorem 12.4.5. With Path Compression, $k$ operations ($\text{find}$ and/or $\text{union}$) take $O(k\alpha(k, \min\{k, n\}))$ time where $\alpha$ is the inverse Ackermann function.

12.4.6.16 Ackermann and Inverse Ackermann Functions

Ackermann function $A(m, n)$ defined for $m, n ≥ 0$ recursively

$$A(m, n) = \begin{cases} 
  n + 1 & \text{if } m = 0 \\
  A(m - 1, 1) & \text{if } m > 0 \text{ and } n = 0 \\
  A(m - 1, A(m, n - 1)) & \text{if } m > 0 \text{ and } n > 0 
\end{cases}$$

$$A(3, n) = 2^{n+3} - 3$$
$$A(4, 3) = 2^{65536} - 3$$

$\alpha(m, n)$ is inverse Ackermann function defined as

$$\alpha(m, n) = \min\{i \mid A(i, \lfloor m/n \rfloor) ≥ \log_2 n\}$$

For all practical purposes $\alpha(m, n) ≤ 5$
12.4.6.17 Lower Bound for Union-Find Data Structure

Amazing result:

**Theorem 12.4.6 (Tarjan).** For **Union-Find**, any data structure in the pointer model requires $\Omega(m\alpha(m,n))$ time for $m$ operations.

12.4.6.18 Running time of Kruskal’s Algorithm

Using Union-Find data structure:

(A) $O(m)$ **find** operations (two for each edge)

(B) $O(n)$ **union** operations (one for each edge added to $T$)

(C) Total time: $O(m \log m)$ for sorting plus $O(m\alpha(n))$ for union-find operations. Thus $O(m \log m)$ time despite the improved Union-Find data structure.

12.4.6.19 Best Known Asymptotic Running Times for MST

Prim’s algorithm using Fibonacci heaps: $O(n \log n + m)$.

If $m$ is $O(n)$ then running time is $\Omega(n \log n)$.

Question Is there a linear time ($O(m + n)$ time) algorithm for MST?

(A) $O(m \log^* m)$ time [Fredman and Tarjan [1987]].

(B) $O(m + n)$ time using bit operations in RAM model [Fredman and Willard [1994]].

(C) $O(m + n)$ expected time (randomized algorithm) [Karger et al. [1995]].

(D) $O((n + m)\alpha(m,n))$ time [Chazelle [2000]].

(E) Still open: Is there an $O(n + m)$ time deterministic algorithm in the comparison model?
