Termination

We need methods to check termination of an equational theory \((\Sigma, E)\). For unconditional equations \(E\) this means proving that the rewriting relation \(\rightarrow_E\) (or, more generally, \(\rightarrow_{E/B}\) for \((\Sigma, E \cup B)\)) is well-founded.

The key observation is that, if we exhibit a well-founded ordering \(>\) on terms such that

\[
(\spadesuit) \quad t \rightarrow_E t' \quad \Rightarrow \quad t > t',
\]

then we have obviously proved termination, since nontermination of \(\rightarrow_E\) would make the order \(>\) non-well-founded.
To show (♣) we need to consider an, infinite number of rewrites \( t \rightarrow_E t' \). We would like to reduce this problem to checking (♣) only for the equations in \( E \). We need:

**Definition:** A well-founded ordering \( > \) on \( \cup_{s \in S} T_\Sigma(V) \) is called a **reduction ordering** iff it satisfies the following two conditions:

- **strict \( \Sigma \)-monotonicity:** for each \( f \in \Sigma \), whenever \( f(t_1, \ldots, t_n), f(t_1, \ldots, t_{i-1}, t'_i, t_{i+1}, \ldots, t_n) \in T_\Sigma(V) \) with \( t_i > t'_i \), we have,

  \[
  f(t_1, \ldots, t_n) > f(t_1, \ldots, t_{i-1}, t'_i, t_{i+1}, \ldots, t_n)
  \]

- **closure under substitution:** if \( t > t' \), then, for any substitution \( \theta : V \rightarrow T_\Sigma(V) \) we have, \( t\theta > t'\theta \).
**Theorem:** Let \((\Sigma, E)\) be an (unconditional) equational theory. Then, \(E\) is terminating iff there exists a reduction order \(>\) such that for each equation \(u = v\) in \(E\) we have, \(u > v\).

**Proof:** The \((\Rightarrow)\) part follows from the observation that, if \(E\) is terminating, the transitive closure \(\xrightarrow{+} E\) of the relation \(\xrightarrow{E}\) is a reduction order satisfying this requirement.

To see \((\Leftarrow)\), it is enough to show that a reduction order with the above property satisfies the implication \((\clubsuit)\). Let \(t \xrightarrow{E} t'\) this means that there is a position \(\pi\) in \(t\), an equation \(u = v\) in \(E\), and a substitution \(\theta\) such that \(t = t[\pi \leftarrow \overline{\theta}(u)]\), and \(t' = t[\pi \leftarrow \overline{\theta}(v)]\). But by closure under substitution we have, \(\overline{\theta}(u) > \overline{\theta}(v)\) and by repeated application of strict \(\Sigma\)-monotonicity we then have, \(t > t'\). q.e.d.
Polynomial Orderings

We are still left with the task of defining suitable reduction orderings. There are several general ways of defining such orderings. One general method is based on polynomial orderings. In its simplest form we can just use polynomials on several variables whose coefficients are natural numbers. For example,

\[ p = 7x_1^3x_2 + 4x_2^2x_3 + 6x_3^2 + 5x_1 + 2x_2 + 11 \]

is one such polynomial. Note that a polynomial \( p \) whose biggest indexed variable is \( n \) (in the above example \( n = 3 \)) defines a function \( p_{\mathbb{N}_+} : \mathbb{N}_+^n \rightarrow \mathbb{N}_+ \), just by evaluating the polynomial on a given tuple of positive numbers. For \( p \) the polynomial above we have for example, \( p_{\mathbb{N}_+}(1, 1, 1) = 35 \).
Note also that we can order the set $\mathbb{N}^n_+$ of functions from $\mathbb{N}^n_+$ to $\mathbb{N}_+$ by defining $f > g$ iff for each $(a_1, \ldots a_n) \in \mathbb{N}^n_+$ $f(a_1, \ldots a_n) > g(a_1, \ldots a_n)$. Notice that this order is well-founded, since if we have an infinite descending chain of functions

$$f_1 > f_2 > \ldots f_n > \ldots$$

by choosing any $(a_1, \ldots a_n) \in \mathbb{N}^n_+$ we would get a descending chain of positive numbers

$$f_1(a_1, \ldots a_n) > f_2(a_1, \ldots a_n) > \ldots f_n(a_1, \ldots a_n) > \ldots$$

which is impossible.
The method of polynomial orderings then consists in assigning to each function symbol $f : s_1 \ldots s_n \rightarrow s$ in $\Sigma$ a polynomial $p_f$ involving exactly the variables $x_1, \ldots x_n$ (all of them, and only them must appear in $p_f$). If $f$ is subsort overloaded, we assign the same $p_f$ to all such overloading. Also, to each constant symbol $b$ we likewise associate a positive number $p_b \in \mathbb{N}_+$. 

Suppose, to simplify notation, that in our set $E$ of equations we have used exactly $k$ different variables, denoted $x_1, \ldots x_k$, each declared with its corresponding sort. Let us denote $X = \{x_1, \ldots x_k\}$. Then our assignment of a polynomial to each function symbol and a number to each constant extends to an $S$-sorted family of functions
Polynomial Orderings (IV)

\[ p_- : T_{\Sigma(X)} \rightarrow \mathbb{N}[X] \]

where \( \mathbb{N}[X] \) denotes the polynomials with natural number coefficients in the variables \( X \), and where \( p_- \) is defined in the obvious, homomorphic way:

- \( p_b = p_b \)
- \( p_{x_i} = x_i \)
- \( p_f(t_1, \ldots, t_n) = p_f(x_1/p_{t_1}, \ldots, x_n/p_{t_n}) \)
Note that the polynomial interpretation $p$ induces a well-founded ordering $>_p$ on the terms of $T_{\Sigma(X)}$ as follows:

$$t >_p t' \iff p_{t_{\mathbb{N}^+}} > p_{t'_{\mathbb{N}^+}}$$

where if $X = \{x_1, \ldots, x_k\}$, we interpret $p_{t_{\mathbb{N}^+}}$ and $p_{t'_{\mathbb{N}^+}}$ as functions in $\mathbb{N}^k_{+\mathbb{N}}$. The relation $>_p$ is clearly an irreflexive and transitive relation on terms in $T_{\Sigma(X)}$, therefore a strict ordering, and is clearly well-founded, because otherwise we would have an infinite descending chain of polynomial functions in $\mathbb{N}^k_{+\mathbb{N}}$, which is impossible.
We now need to check that this ordering is furthermore: (i) strictly $\Sigma$-monotonic, and (ii) closed under substitution. Condition (i) follows easily from the fact that for each function symbol $f : s_1 \ldots s_n \rightarrow s$ in $\Sigma$ $p_f$ involves exactly the variables $x_1, \ldots x_n$ and has all its coefficients in $\mathbb{N}_+$. Therefore, $p_{f_{\mathbb{N}_+}}$, viewed as a function of $n$ arguments, is strictly monotonic in each of its arguments. Condition (ii) follows from the following general property of the $p_-$ function, which is left as an exercise:

$$p_t(x_1/u_1, \ldots, x_n/u_n) = p_t(x_1/p_{u_1}, \ldots, x_n/p_{u_n}).$$

This then easily yields that if $t >_p t'$ then

$$t(x_1/u_1, \ldots, x_n/u_n) >_p t'(x_1/u_1, \ldots, x_n/u_n),$$

as desired.
Therefore, polynomial interpretations of this kind define reduction orderings and can be used to prove termination. Consider for example the single equation $f(g(x)) = g(f(x))$ in an unsorted signature having also a constant $a$. Is this equation terminating? We can prove that it is so by the following polynomial interpretation:

- $p_f = x_1^3$
- $p_g = 2x_1$
- $p_a = 1$

since we have the following strict inequality of functions: $((2x)^3)_{\mathbb{N}_+} > (2(x^3))_{\mathbb{N}_+}$, showing that $f(g(x)) >_p g(f(x))$. 
A second class of reduction orderings are based on the idea of defining such orderings from some **minimal information** such as giving an ordering on the function symbols in $\Sigma$, which is then extended to a reduction ordering on all terms. Since if $\Sigma$ is finite the number of possible orderings between function symbols in $\Sigma$ is also finite, checking whether a proof of termination exists this way can be **automated**. One such method is the **lexicographic path ordering**.

The intuitive idea that functions that are more complex should be bigger in the ordering (for example: $\_\times\_ > \_+\_ > s$) tends to work quite well, and can yield a reduction ordering containing the equations. But since there is a finite number of possible orderings, a tool can try them all.
The Lexicographic Path Ordering (II)

**Definition:** Given a finite signature $\Sigma$ an an ordering $>$ of its symbols, then the lexicographic path ordering $>_{lpo}$ on $\bigcup_{s \in S} T_{\Sigma}(V)$ is defined recursively as follows:

- if $x \in \text{vars}(t)$ and $x \neq t$, then $t >_{lpo} x$.

- $f(t_1, \ldots, t_n) >_{lpo} g(t'_1, \ldots, t'_m)$ if either:
  - for some $i$, $t_i >_{lpo} g(t'_1, \ldots, t'_m)$, or
  - $f > g$ and $f(t_1, \ldots, t_n) >_{lpo} t'_j$, for all $j$, or
  - $f = g$, $f(t_1, \ldots, t_n) >_{lpo} t'_j$, for all $j$, and there exist an $i$, $1 \leq i \leq n$, such that, $t_j = t'_j$, $1 \leq j < i$, and $t_i >_{lpo} t'_i$. 

The Lexicographic Path Ordering (III)

It can be shown (for a detailed proof see the book by Baader and Nipkow cited later) that for a finite signature $\Sigma$ LPO is a reduction order. We can therefore use it to prove termination.

Consider for example the usual equations for natural number addition: $n + 0 = n$ and $n + s(m) = s(n + m)$. We can prove that they are terminating by using the LPO associated to the ordering $+ > s > 0$. Indeed, it is then trivial to check that $n + 0 >_{lpo} n$ and $n + s(m) >_{lpo} s(n + m)$. 
Since when rewriting modulo axioms we are rewriting equivalence classes, some orderings may not be appropriate, because they may give different results on different representatives of the equivalence class. For example, the lexicographic path order may lead to such conflicts, because of the strict left-to-right order used on the list of subterms, violated by commutativity.

What we need is an order compatible with the axioms, so that it defines also an order on the set, $\cup_{s \in S} T_{\Sigma/A}(X)$. Such orders do exist. For example, an order treating the subterms as a multiset, instead than as a list, may be compatible with a commutativity axiom.
Some polynomial interpretations may also be compatible with certain axioms. For example, a symmetric polynomial such that \( p(x, y) = p(y, x) \) is compatible with commutativity and can therefore be used to interpret a commutative symbol. For example, \( 2x^3 + 2y^3 \) is symmetric. Similarly, a polynomial \( p(x, y) \) which is symmetric (\( p(x, y) = p(y, x) \)) and furthermore satisfies the associativity equation

\[ p(x, p(y, z)) = p(p(x, y), z) \]

can be used to interpret an associative-commutative symbol. As shown by Bencherifff and Lescanne the polynomials satisfying these two conditions have a simple characterization: they must be of the form \( axy + b(x + y) + c \) with \( ac + b - b^2 = 0 \).
The Maude Termination Tool (MTT) is a tool that can be used to prove the operational termination of Maude functional modules. In general, such modules can be conditional and may be not just order-sorted, but membership equational theories.

They may involve axioms like associativity and commutativity; and they may also have evaluation strategies (see Maude 2.2 manual, Section 4.4.7) indicating what arguments of a function symbol should be evaluated before applying equations for that symbol. For example, in an `if_then_else_fi` the first argument should be evaluated before equations for it are applied; and in a “lazy list cons” `_;_` the first argument is evaluated, but not the second.
Features such as sorts, subsorts, memberships, and evaluation strategies may be essential for the termination of a Maude module. That is, ignoring them may result in a nonterminating module.

To preserve these features somehow, while still allowing using standard termination backend tools, the MTT implements the transformations of \((\Sigma, E)\) first into an unsorted conditional theory \((\Sigma^\circ, E^\circ)\), and then \((\Sigma^\circ, E^\circ)\) is transformed into an unsorted unconditional theory \((\Sigma^\bullet, E^\bullet)\).

If the module declares evaluation strategies, they are also transformed; but at the end evaluation strategies can either be used directly by a termination tool like Mu-Term, or a further theory transformation can eliminate such strategies.
The course web page indicates where MTT has been installed. By typing: `./MTT` and carriage return the tool’s GUI comes up and the user can interact with it. By using the File menu one can enter a Maude module into the tool.

Once a Maude module (enclosed in parentheses, and not importing any built-in modules) has been entered, the user can perform the theory transformation \((\Sigma, E) \mapsto (\Sigma^\bullet, E^\bullet)\) in one of three increasingly simpler modes: (1) **Complete**; (2) **No Kinds**; and (3) **No Sorts**. In case (2) kinds are ignored; and in case (3) both kinds and sorts are ignored. There is a tradeoff between simplicity of the transformation and its tightness. Sometimes a simpler transformation works better, and sometimes a more complete one is essentially needed.
The choice of transformation can be made by clicking the appropriate buttons (a screenshot will show this). But one also needs to choose which backend termination tool for unsorted and unconditional specifications will be used. One among the CiME, MU-TERM, and AProVE termination tools can be chosen.

Then one can click on the Check bar to check the specification with the chosen tool. Some of these tools offer choices for different settings. So, we can try to prove termination using three different transformation variants, and then with one of three backend tools, sometimes customizing the particular tool choices. This maximizes the chances of obtaining a successful termination proof.
The MTT Tool (V)

What the tool then demonstrates is that the original Maude functional module is operationally terminating. The correctness of such a proof is based on:

- the correctness of the theory transformations (see paper in course web page); and

- the correctness of the chosen tools, that sometimes output a justification of how they proved termination.

A screenshot of a tool interaction is given in the next page.
(fmod PEANO is
  sort Nat .
  op 0 : Nat -> Nat [ctor].
  op s : Nat -> Nat [ctor].
  op plus : Nat Nat -> Nat .
  vars M N : Nat .
  eq plus(M, s(N)) = s(plus(M, N)) .
  eq plus(M, 0) = M
  op times : Nat Nat -> Nat .
  eq times(M, s(N)) = plus(times(M, N), M) .
  eq times(M, 0) = 0 .
  endfm)

We obtain no new DP problems.

Termination of R successfully shown.

Duration:
0:00 minutes
All the termination tools try to prove that a set of equations $E$, conditional or unconditional, is terminating by applying different proof methods; for example by trying to see if particular orderings can be used to prove the equations terminating.

But these termination proof methods are not decision procedures: in general termination of a set of equations (even if they are unconditional) is undecidable. However, termination is decidable for finite sets of unconditional equations $E$ such that both the lefthand and the righthand sides are ground terms, or even if just the righthand sides are ground terms (see Chapter 5 in Baader and Nipkow, “Term Rewriting and All That”, Cambridge U.P.).
Where to Go from Here

Besides lexicographic path ordering there are many other ordering that can be used to prove termination. Two good sources, with references to the general literature, are:

Furthermore, the Ölveczky lecture notes contain a very good introduction to termination with many examples.
