More on Reachability Homomorphisms

Recall that given two \((\Sigma, \phi)\)-reachability models \(A_\rightarrow = (A, \rightarrow_A)\), and \(B_\rightarrow = (B, \rightarrow_B)\), a \((\Sigma, \phi)\)-reachability homomorphism \(h : A_\rightarrow \rightarrow B_\rightarrow\) is a \(\Sigma\)-homomorphism \(h : A \rightarrow B\) such that “preserves reachability,” that is, for each \(k \in K\), \(a \rightarrow_{A,k} a'\) implies \(h_k(a) \rightarrow_{B,k} h_k(a')\).

We call a reachability homomorphism \(h : A_\rightarrow \rightarrow B_\rightarrow\) a (stuttering) bisimulation if, in addition, for each \(k \in K\), and each \(a \in A_k\), \(h_k(a) \rightarrow_{B,k} b'\) implies that there exists \(a' \in A_k\) such that: (i) \(h_k(a') = b'\), and (ii) \(a \rightarrow_{A,k} a'\). That is, a bisimulation preserves reachability “in both directions.”
More on Reachability Homomorphisms (II)

Recall that, given any $(\Sigma, \phi)$-reachability model $\mathcal{A}_\rightarrow = (\mathcal{A}, \rightarrow_\mathcal{A})$ a kind $k$ and an element $a \in A_k$, we defined $\text{Reach}_{\mathcal{A}_\rightarrow} (a) = \{ x \in A_k \mid a \rightarrow_\mathcal{A} x \}$.

The following lemma is left as an easy exercise.

**Lemma 1.** If $h : \mathcal{A}_\rightarrow \longrightarrow \mathcal{B}_\rightarrow$ is a reachability homomorphism (resp. a bisimulation) then for each kind $k$ and an element $a \in A_k$ we have $h_k[\text{Reach}_{\mathcal{A}_\rightarrow} (a)] \subseteq \text{Reach}_{\mathcal{B}_\rightarrow} (h(a))$ (resp. $h_k[\text{Reach}_{\mathcal{A}_\rightarrow} (a)] = \text{Reach}_{\mathcal{B}_\rightarrow} (h(a))$).
Recall that, given a \((\Sigma, \phi)\)-reachability model \(A_\rightarrow = (A, \rightarrow_A)\) having a Boolean predicate \(I\) with arguments of kind \(k\) we defined \([|I|]_{A_\rightarrow} = \{ x \in A_k | I_A(x) = true_A \}\).

We say that a \((\Sigma, \phi)\)-reachability model \(A_\rightarrow = (A, \rightarrow_A)\), where \(\Sigma\) contains the sort \(\text{Bool}\) with constants \(true\) and \(false\) protects \(\text{Bool}\) if \(A_{\text{Bool}} = \{true_A, false_A\}\), and \(true_A \neq false_A\).

**Lemma 2.** Suppose now that we have \((\Sigma, \phi)\)-reachability models \(A_\rightarrow = (A, \rightarrow_A)\), and \(B_\rightarrow = (B, \rightarrow_B)\) that both protect \(\text{Bool}\). Then, any \((\Sigma, \phi)\)-reachability homomorphism \(h : A_\rightarrow \rightarrow B_\rightarrow\) must satisfy: (i) \(h_k[|[I]|_{A_\rightarrow}] \subseteq [|[I]|_{B_\rightarrow}]\), and (ii) \(h_k^{-1}[|[I]|_{B_\rightarrow}] = [|[I]|_{A_\rightarrow}]\).
More on Reachability Homomorphisms (IV)

**Proof:** By assumption $I$ is a Boolean predicate in both $A\rightarrow$ and $B\rightarrow$, and since both protect $Bool$, for each $a \in A_k$ either $I_A(a) = true_A$, or $I_A(a) = false_A$. Likewise, for each $b \in B_k$ either $I_B(b) = true_B$, or $I_B(b) = false_B$. Of course, since $h$ is a homomorphism, we have $h(true_A) = true_B$, and $h(false_A) = false_B$, which trivially implies (i). Applying $h_k^{-1}$ to both sides of (i) we get the containment: $h_k^{-1}[h_k[[|I|]_{A\rightarrow}]] \subseteq h_k^{-1}[[|I|]_{B\rightarrow}]$, which trivially gives us the containment $[[|I|]_{A\rightarrow} \subseteq h_k^{-1}[[|I|]_{B\rightarrow}]$. So, to prove (ii) we just need to show $h_k^{-1}[[|I|]_{B\rightarrow}] \subseteq [|I|]_{A\rightarrow}$. To see this containment, suppose that $a \in A_k$ is such that $I_B(h_k(a)) = true_B$. We reason by contradiction. Suppose $I_A(a) = false_A$. Since $h$ is a homomorphism we must have $h(I_A(a)) = I_B(h_k(a)) = false_B$, a contradiction. q.e.d.
The lemmas we have been assembling can be put to good use to prove invariants. The point is that reachability homomorphisms allow us to shift our ground in the verification process. Using a reachability homomorphism \( h : A \rightarrow \rightarrow B \rightarrow \rightarrow \) we can reduce proving an invariant for \( A \rightarrow \rightarrow \) (which may be infinite-state or too big) to proving an invariant for \( B \rightarrow \rightarrow \) (which may be finite-state or smaller).

**Theorem.** Suppose now that we have a \((\Sigma, \phi)\)-reachability homomorphism \( h : A \rightarrow \rightarrow B \rightarrow \rightarrow \) and that both \( A \rightarrow \rightarrow = (A, \rightarrow_A) \), and \( B \rightarrow \rightarrow = (B, \rightarrow_B) \) protect \textit{Bool}. Then, for any Boolean predicate in \( \Sigma \) we have the implication

\[
B \rightarrow \rightarrow, h(a) \models \square I \quad \Rightarrow \quad A \rightarrow \rightarrow, a \models \square I
\]

Furthermore, if \( h \) is a bisimulation this is an equivalence.
Proof: By definition, we have to prove the implication:

\[ \text{Reach}_{B\_}(h(a)) \subseteq [\lVert I \rVert]_{B\_} \quad \Rightarrow \quad \text{Reach}_{A\_}(a) \subseteq [\lVert I \rVert]_{A\_} \]

But by Lemma 2, applying \( h^{-1} \) to both sides of the hypothesis we get,
\[ h^{-1}[\text{Reach}_{B\_}(h(a))] \subseteq [\lVert I \rVert]_{A\_}. \]

And by Lemma 1 we have,
\[ h^{-1}[h(\text{Reach}_{A\_}(a))] \subseteq h^{-1}[\text{Reach}_{B\_}(h(a))], \]

which together with the trivial containment
\[ \text{Reach}_{A\_}(a) \subseteq h^{-1}[h(\text{Reach}_{A\_}(a))], \]
give us
\[ \text{Reach}_{A\_}(a) \subseteq [\lVert I \rVert]_{A\_}, \]
as desired. If, in addition, \( h \) is a bisimulation and we have
\[ \text{Reach}_{A\_}(a) \subseteq [\lVert I \rVert]_{A\_}, \]
then by Lemmas 1 and 2 we have,
\[ \text{Reach}_{B\_}(h(a)) = h_k[\text{Reach}_{A\_}(a)] \subseteq h[[\lVert I \rVert]_{A\_}] \subseteq [\lVert I \rVert]_{B\_}, \]
as desired. q.e.d.
A very simple method to exploit the above theorem is to use an **equational abstraction**. The idea is enormously simple. Suppose that our system has been specified by means of an equational theory \( R = (\Sigma, E, \phi, R) \) which we assume satisfies all the executability conditions and protects the sort Bool. We can then **add new equations**, say \( G \) to \( R \) to obtain a rewrite theory \( R/G = (\Sigma, E \cup G, \phi, R) \). Now consider the initial model \( T_{R/G} \). By construction \( T_{R/G} \) satisfies \( E \cup G \) (in particular \( E \)), and \( R \). Therefore, by the initiality theorem for \( T_R \) we have a unique reachability homomorphism

\[
eval_{T_{R/G}}^R : T_R \rightarrow T_{R/G}
\]

mapping each \([t]_E\) to \([t]_{E \cup G}\). We call \( T_{R/G} \) the **equational abstraction** by equations \( G \) of \( T_R \).
Suppose that $\mathcal{R}/G$ protects $\text{Bool}$. Then, for any invariant $I$ of interest, our previous theorem immediately applies to give as an implication:

$$\mathcal{T}_{\mathcal{R}/G}, [t]_{E \cup G} \models \Box I \Rightarrow \mathcal{T}_{\mathcal{R}, [t]_E} \models \Box I$$

Therefore, we can use the equational abstraction $\mathcal{T}_{\mathcal{R}/G}$, which typically is much smaller and can even be finitely reachable when $\mathcal{T}_{\mathcal{R}}$ is infinitely reachable, to verify the invariant $\mathcal{T}_{\mathcal{R}, [t]_E} \models \Box I$. But to do this in Maude we need, besides checking the requirement that $\mathcal{R}/G$ protects $\text{Bool}$, to also check that $\mathcal{R}/G$ satisfies the usual executability requirements, namely, that it is ground confluent, sort decreasing, and terminating, and also that it is ground coherent.
We can illustrate the power of equational abstractions with our readers and writers example, for which we already performed bounded model checking of invariants up to depth $10^6$ in Lecture 22. Since the Maude Church-Rosser Checker and Coherence Checker tools do not currently allow built-in submodules like NAT or BOOL, we will consider the following slight variants of our original specifications that do not use any built-ins.

mod R&W is
    sort Nat Config .
    op <_,_> : Nat Nat -> Config [ctor] . --- readers/writers
    op 0 : -> Nat [ctor] .
    op s : Nat -> Nat [ctor] .
    vars R W : Nat .
rl < 0, 0 > => < 0, s(0) > .
rl < R, s(W) > => < R, W > .
rl < R, 0 > => < s(R), 0 > .
rl < s(R), W > => < R, W > .

endm

mod R&W-PREDS is
  protecting R&W .
sort NewBool .
ops mutex one-writer : Config -> NewBool [frozen] .
eq mutex(< s(N:Nat),s(M:Nat) >) = ff .
eq mutex(< 0,N:Nat >) = tt .
eq mutex(< N:Nat,0 >) = tt .
eq one-writer(< N:Nat,s(s(M:Nat)) >) = ff .
eq one-writer(< N:Nat,0 >) = tt .
eq one-writer(< N:Nat,s(0) >) = tt .
endm
We can then drastically collapse the set of states by defining the following equational abstraction, which we can immediately use to verify our two invariants:

```plaintext
mod R&W-ABS is
  including R&W-PREDS .
  eq < s(s(N:Nat)),0 > = < s(0),0 > .
endm
```

search in R&W-ABS : < 0,0 > =>* C:Config such that

```plaintext
mutex(C:Config) = ff .
```

No solution.

search in R&W-ABS : < 0,0 > =>* C:Config such that

```plaintext
one-writer(C:Config) = ff .
```

No solution.
A Readers&Writers Example (III)

Since Maude computes really in the canonical reachability model $C_R$ of the given rewrite theory $\mathcal{R}$ which is only isomorphic to the initial model $T_R$ under the required executability assumptions, in reality we are not yet finished verifying that our original readers and writers system satisfies the two invariants using the above equational abstraction. We furthermore need to show that:

1. both R&W-PREDS and R&W-ABS protect NewBool;

2. R&W-ABS is ground confluent, sort-decreasing, and terminating; and

3. R&W-ABS is ground coherent.
Note that we can easily show (1): that both R&W-PREDS and R&W-ABS protect \text{NewBool}, by showing that: (i) both are ground confluent, sort-decreasing, and terminating; and (ii) both are sufficiently complete. Indeed, by (i), the canonical term algebra by the equations is isomorphic to the initial algebra; and by (ii), the only canonical terms of sort \text{NewBool} must be the constructors \texttt{tt} and \texttt{ff}, which are both in canonical form, and therefore different. Note also that (i) above shows (2) as well.
We can check local confluence and sort-decreasingness of R&W-PREDs and R&W-ABS with the CRC tool:

Maude> (check Church-Rosser R&W-PREDs .)
Checking solution:
   All critical pairs have been joined. The specification is locally-confluent.
   The specification is sort-decreasing.

Maude> (check Church-Rosser R&W-ABS .)
Checking solution:
   All critical pairs have been joined. The specification is locally-confluent.
   The specification is sort-decreasing.
A Readers&Writers Example (VI)

Since the termination of the equations in R&W-ABS implies that of the (fewer) equations in R&W-PREDs, it is enough to check the first module. After extracting a functional module with the equations from R&W-ABS and with a slight change of syntax and using AProVe through the MTT tool (with no sort information) we get:

(fmod RWABS is

  sort Nat Config .
  op s : Nat -> Nat [ctor] .
  vars R W : Nat .

  sort NewBool .

opt mutex : Config -> NewBool .
opt one-writer : Config -> NewBool .

vars M N : Nat .

eq mutex(cfg(s(N), s(M))) = ff .
eq mutex(cfg(zero, N)) = tt .
eq mutex(cfg(N, zero)) = tt .
eq one-writer(cfg(N, s(s(M)))) = ff .
eq one-writer(cfg(N, zero)) = tt .
eq one-writer(cfg(N, s(zero))) = tt .
eq cfg(s(s(N)), zero) = cfg(s(zero),zero) .

endfm)

*** AProVe output

Termination of R to be shown.
Removing the following rules from R which fulfill a polynomial ordering:

\[
\begin{align*}
\text{and}(tt, X) & \rightarrow X \\
\text{mutex}(\text{cfg}(s(N), s(M))) & \rightarrow \text{ff} \\
\text{one} - \text{writer}(\text{cfg}(N, s(\text{zero}))) & \rightarrow tt \\
\text{one} - \text{writer}(\text{cfg}(N, s(s(M)))) & \rightarrow \text{ff}
\end{align*}
\]

where the Polynomial interpretation:

\[
\begin{align*}
\text{POL}(\text{and}(x_1, x_2)) &= x_1 + x_2 \\
\text{POL}(\text{ff}) &= 0 \\
\text{POL}(\text{mutex}(x)) &= x \\
\text{POL}(\text{tt}) &= 1 \\
\text{POL}(s(x)) &= 1 + x
\end{align*}
\]
\[
\begin{align*}
\text{POL}(\text{cfg}(x_0_1, x_0_2)) &= x_0_1 + x_0_2 \\
\text{POL}(x_0_1 - x_0_2) &= x_0_1 + x_0_2 \\
\text{POL}(\text{one}) &= 0 \\
\text{POL}(\text{zero}) &= 1 \\
\text{POL}(\text{writer}(x_0_1)) &= x_0_1
\end{align*}
\]

was used.

Not all Rules of R can be deleted, so we still have to regard a part of R.

R contains no Dependency Pairs and therefore no SCCs.

Termination of R successfully shown.

Duration:
0:00 minutes
Next we can use the SCC Tool to check the sufficient
completeness of \texttt{R&W-PREDS} and \texttt{R&W-ABS} which, together
with the confluence and termination checks already
performed ensures that \texttt{R&W-PREDS} and \texttt{R&W-ABS} protect \texttt{BOOL}.

\begin{verbatim}
Maude> load scc
Maude> (scc R&W-PREDS .)
Checking sufficient completeness of R&W-PREDS ...
Success: R&W-PREDS is sufficiently complete under the assumption that it is
  weakly-normalizing, confluent, and sort-decreasing.
Maude> (scc R&W-ABS .)
Checking sufficient completeness of R&W-ABS ...
Success: R&W-ABS is sufficiently complete under the assumption that it is
  weakly-normalizing, confluent, and sort-decreasing.
\end{verbatim}
The only remaining check is the ground coherence of R&W-ABS. Using the ChC tool get get:

Maude> (check coherence R&W-ABS .)
   The following critical pairs cannot be rewritten:
   cp < s(0),0 >
   => < s(N*@:Nat),0 > .

Ground coherence requires that all ground instances of such a pair can indeed be rewritten in one step by the rules. We can reason by cases and consider the canonical forms by our equation of the following instances of the righthand side:

- \text{can}(< s(0),0 >) = < s(0),0 >
- \text{can}(< s(s(N:\text{Nat})),0 >) = < s(0),0 >
A Readers & Writers Example (IX)

So, all boils down to checking whether we can rewrite the term \(< s(0), 0 >\) to \textit{itself} in one step with the rules of the module, up to canonical form. This is indeed the case, since using rule

\[ rl < R, 0 > \Rightarrow < s(R), 0 >. \]

we can rewrite \(< s(0), 0 >\) to \(< s(s(0)), 0 >\), whose canonical form is \(< s(0), 0 >\).
