Universal Turing Machines & Church-Turing Thesis
• DFA with (infinite) tape.
• One move: read, write, move, change state.
Transition Function

\[ \delta: Q \times \Gamma \rightarrow Q \times \Gamma \times \{L, R, S\} \]

- current state
- symbol scanned
- new state
- symbol to write
- direction to move on tape

\[ \delta(q, a) = (p, b, L) \]

from state \( q \), on reading \( a \):
- go to state \( p \)
- write \( b \)
- move head Left
TM programming tricks

• checking off symbols
• shifting over
• using finite control memory
• subroutine calls

TM “extensions”

• 2-way infinite tape
• multiple tracks
• multiple tapes
• multi-dimensional TMs
Example/Refresher

TM that adds two unary numbers.

7 + 4: $0000000#0000$ initial tape contents

= 11: $000000000000$ final tape contents

Strategy?

• go right to first blank, turning # into 0
• back up one cell, erase 0
• return to first cell
Example/Refresher

7 + 4:  \$0000000#0000  initial tape contents

Strategy?
• go right to first blank, turning # into 0
  \(\delta(q_0, 0) = (q_0, 0,R)\)
  \(\delta(q_0, #) = (q_0, 0,R)\)
• back up one cell, erase 0
  \(\delta(q_0, B) = (q_1, B,L)\)
  \(\delta(q_1, 0) = (q_2, B,L)\)
• return to first cell
  \(\delta(q_2, 0) = (q_2, 0,L)\)
  \(\delta(q_2, \$) = (q_{halt}, \$,R)\)
**Special purpose machines?**

- Different DFA for different languages (duh)
- Different TMs for different languages, functions.
- Early computer programming was no different
Von Neumann Architecture

- stored-program computer
  - programs can be data!
  - program-as-data determines subcircuits to employ
- fetch-decode-execute cycle
- hence, one computer can behave like any

“I know that in or about 1943 or '44 von Neumann was well aware of the fundamental importance of Turing's paper of 1936 ... Von Neumann introduced me to that paper and at his urging I studied it with care. Many people have acclaimed von Neumann as the "father of the computer" (in a modern sense of the term) but I am sure that he would never have made that mistake himself. He might well be called the midwife, perhaps, but he firmly emphasized to me, and to others I am sure, that the fundamental conception is owing to Turing— in so far as not anticipated by Babbage ... “

- Stan Frankel – Los Alamos
Universal TM

• A single TM $M_u$ that can compute anything computable!
• Takes as input
  – the \textit{description} of some other TM $M$
  – data $w$ for $M$ to run on
• Outputs
  – the results of running $M(w)$

Need to make precise what the \textit{description} of a TM is
Coding of TMs

• Show how to represent every TM as a natural number

• Lemma: If $L$ over alphabet $\{0,1\}$ is accepted by some TM $M$, then there is a one-tape TM $M'$ that accepts $L$, such that
  – $\Gamma = \{0,1,B\}$
  – states numbered $1, \ldots, k$
  – $q_1$ is the unique start state
  – $q_2$ is the unique halt/accept state
  – $q_3$ is the unique halt/reject state

• So, to represent a TM, we need only list its set of transitions – everything else is implicit by above
Listing Transition

- Use the following order:
  \( \delta(q_1,0), \delta(q_1,1), \delta(q_1,B), \delta(q_2,0), \delta(q_2,1), \delta(q_2,B), \ldots \)
  
  \( \ldots \delta(q_k,0), \delta(q_k,1), \delta(q_k,B) \).

- Use the following encoding:
  \[ 111 \ t_1 \ 11 \ t_2 \ 11 \ t_3 \ 11 \ \ldots \ 11 \ t_{3k} \ 111 \]

  where \( t_i \) is the encoding of transition \( i \) as given on the next slide.
Encoding a transition

Recall transition looks like $\delta(q,a) = (p, b, L)$

So, encode as

<state> 1 <input> 1 <new state> 1 <new-symbol> 1 <direction>

where

- state $q_i$ represented by $0^i$
- 0, 1, B represented by 0, 00, 000
- L, R, S represented by 0, 00, 000

$\delta(q_3, 1) = (q_4, 0, R)$ represented by 0001001000010100
Typical TM code:

\[
11101010000100100110100100000101011\ldots11\ldots11\ldots111
\]

- Begins, ends with **111**
- Transitions separated by **11**
- Fields within transition separated by **1**
- Individual fields represented by 0s
**TM are (binary) numbers**

- Every TM is encoded by a unique element of N.
- Convention: elements of N that do not correspond to any TM encoding represent the “null TM” that accepts nothing.
- Thus, every TM is a number, **and vice versa**.
- Let \(<M>\) mean the number that encodes \(M\).
- Conversely, let \(M_n\) be the TM with encoding \(n\).
Universal TM $M_u$

Construct a TM $M_u$ such that

$$L(M_u) = \{ <M> \# w \mid M \text{ accepts } w \}$$

Thus, $M_u$ is a stored-program computer.
It reads a program $<M>$ and executes it on data $w$

$M_u$ simulates the run of $M$ on $w$

A single TM captures the notion of “computable”!!
How $M_u$ works

3 tapes
- Tape 1: holds input $M$ and $w$; never changes
- Tape 2: simulates $M$'s single tape
- Tape 3: holds $M$'s current state
Universal TM  $M_u$

**Phase 1:** Check if $<M>$ is a valid TM on tape 1
- No four 1’s in a row
- Three initial, ending 1’s
- Substring $110^i10^j1$ doesn’t appear twice
- Appropriate number of 0’s between 1’s in transition codes: 110000101000000100001...
  (0000 does not encode a 0,1, or B to write)
- Could check that transitions are in right order, and form a complete set (but not necessary)
- Etc.

If not valid, then halt and reject
Phase 2: Set up

– copy $w$ to tape 2, with head scanning first symbol
– write 0 on tape 3 indicating $M$ is in start state $q_1$

Tape 1

\[
\textbf{11101010000100100110100100000101011\ldots111 \# 100110}
\]

Code for $M$

Tape 2

\[
\textbf{\$100110}
\]

Current contents of $M$’s tape

Tape 3

\[
\textbf{\$0}
\]

Current state of $M$

If at any time, Tape 3 holds 00 (or 000), then halt and accept (or reject)
**Phase 3:** Repeatedly simulate steps of $M$

Where in code is next transition?

- **Tape 1:**
  - Code for $M$:
    - $111010100001001001101001000001010011\ldots111\ #\ 100110$

- **Tape 2:**
  - Current contents of $M$'s tape:
    - $100110$

- **Tape 3:**
  - Current state of $M$:
    - $0$

If tape 3 holds $0^i$ and tape 2 is scanning 1, then search for substring $110^i1001$ on tape 1

- **What to do next:**
  - copy new state 00000 to tape 3
  - write a 0 under tape 2's head
  - move tape 2 head to the right
Phase 3: After the single move

Tape 1

1110101000110010011010010000010100111111 # 100110

Code for M

Tape 2

$000110

Current contents of M’s tape

Tape 3

$00000

Current state of M

Check if 00 or 000 is on tape 3; if so, halt and accept or reject

Otherwise, simulate the next move by searching for pattern.

In this example, the next pattern = 11000000101
Towards “real” computers: RAMs

Random Access Machine:
• finite number of arithmetic registers
• infinite number of memory locations
• instruction set (next page)
• program instructions written in continuous block of memory starting at location 1 and all registers set to 0.
## RAM instruction set

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add X, Y</td>
<td>Add contents of register X and Y, and place result in register X</td>
</tr>
<tr>
<td>LOADC X, num</td>
<td>Place constant num in register X</td>
</tr>
<tr>
<td>LOAD X, M</td>
<td>Put contents of memory loc M into register X</td>
</tr>
<tr>
<td>LOADI X, M</td>
<td>Indirect addressing: put value(value(M)) into register X</td>
</tr>
<tr>
<td>STORE X, M</td>
<td>Copy contents of reg X into mem location M</td>
</tr>
<tr>
<td>JUMP X, M</td>
<td>If register X = 0, then next instruction is at memory location M (otherwise, next instruction is the one following the current one, as usual)</td>
</tr>
<tr>
<td>HALT</td>
<td>Halt (duh)</td>
</tr>
</tbody>
</table>
TM can simulate RAMs

- Can write a “TM-interpreter” of RAM code. Thus, no more TM programming.
- Actual simulation has low overhead (though memory is not random-access).
TM tapes

• Instruction-location tape
  – stores memory location where next instruction is
  – initially contains only “1”

• Register tape
  – stores register numbers and their contents, as follows: # <reg-num> # <contents> # .. etc.
  – Example: suppose R1 has 11, and R4 has 101, and all other registers are empty. Then register tape:

  $ # 1, 1 1 # 1 0 0 , 1 0 1 # . . .
**TM tapes**

- Memory tape – similar to register tape, but can hold numbers, OR instructions:
  - numbers:  `# <mem-location> , <value> #` ...
  - instructions:
    - example: mem location 101 holds ADD 3,6

```
# 1 0 1 , ADD , 1 1 , 1 1 0 #  .  .  .
```

- 5 work tapes
**TM setup**

- Blank register tape
- Memory tape holds RAM program, starting at memory location 1. No other data stored.
- 1 on instruction-location tape
**TM step overview**

(many TM steps for each RAM step)

- Read instruction-location tape
- search memory tape for the instruction
- execute the instruction, changing register and memory tapes as needed
- update the location-instruction tape

In other words, it goes through a fetch-decode-execute cycle
Example

• Suppose instruction location tape holds only:

\[
\begin{array}{cccccccc}
\$ & 1 & 0 & 1 & & & & \\
\end{array}
\]

• Scan memory tape, looking for “# 1 0 1 ,”
  Suppose it finds

\[
\begin{array}{cccccccc}
. & . & # & 1 & 0 & 1 & , & A D D & , & 1 & 1 & , & 1 & 1 & 0 & # \\
\end{array}
\]

• It finds “ADD” following “,” and switches to special state \( q_{add} \) to handle the addition
Example (cont.)

- first argument is in register 11 so search register tape for:

  # 1 0 1, ADD, 1 1, 1 1 0 #

- then copy <bitstring> to worktape 1
- similarly, search for, find, place value of register 110 onto worktape 2
Example (cont.)

• Now go to subroutine to add worktape 1 + worktape 2, place results on worktape 3.
• Result must go back into register 11
• Search register tape again for

<table>
<thead>
<tr>
<th></th>
<th>#</th>
<th>1</th>
<th>1</th>
<th>,</th>
<th>&lt;bitstring&gt;</th>
</tr>
</thead>
</table>

• Replace <bitstring> with new value copied from worktape 3, shifting as necessary
• Add 1 to instruction-location tape
RAM simulation

- MANY details left out
- Other types of instructions are similar
- Number of steps to simulate RAM?
- Delicate issue.... does RAM actually have constant-time access to infinite memory?
- Can show (beyond this course) for “reasonable” time model on a RAM, if $T(n)$ steps are required, then on a TM, only $T(n)^2$ steps. ($T(n)^3$ if RAM has mult. and div.)
Church-Turing thesis

- TMs capture notion of "computable"
- Evidence
  - RAM computer
  - general recursive functions (Gödel & Herbrand)
    - constant/projection/successor/composition/recursion
  - $\lambda$-calculus (Church) for defining functions (CS 421)
  - general string-rewriting-system
    - unrestricted grammar, productions of form $\alpha \rightarrow \beta$ for any $\alpha$ and $\beta$
  - attempts to extend TMs

All give you exactly the TM-computable functions
DFA parts
TM tape for cut-paste

$ \cdot \cdot \cdot \cdot \cdot \cdot \# \cdot \cdot \cdot$

Blah blah blah
