What the Kinect does

Get Depth Image

Estimate Body Pose

Application (e.g., game)
How Kinect Works: Overview

- IR Projector
- IR Sensor
- Projected Light Pattern
- Stereo Algorithm
- Segmentation, Part Prediction
- Depth Image
- Body Pose
Part 1: Stereo from projected dots

IR Projector → Projected Light Pattern

IR Sensor

Stereo Algorithm → Depth Image

Segmentation, Part Prediction → Body Pose
Part 1: Stereo from projected dots

1. Overview of depth from stereo

2. How it works for a projector/sensor pair

3. Stereo algorithm used by Primesense (Kinect)
Depth from Stereo Images

Dense depth map

Some of following slides adapted from Steve Seitz and Lana Lazebnik
Depth from Stereo Images

• Goal: recover depth by finding image coordinate $x'$ that corresponds to $x$
Depth from disparity

\[
\frac{x - x'}{O - O'} = \frac{f}{z}
\]

Disparity is inversely proportional to depth.

\[
disparity = x - x' = \frac{B \cdot f}{z}
\]
Potential matches for $x$ have to lie on the corresponding line $l'$. 

Potential matches for $x'$ have to lie on the corresponding line $l$. 

Stereo and the Epipolar constraint
Simplest Case: Parallel images

- Image planes of cameras are parallel to each other and to the baseline
- Camera centers are at same height
- Focal lengths are the same
- Then, epipolar lines fall along the horizontal scan lines of the images
Basic stereo matching algorithm

- If necessary, rectify the two stereo images to transform epipolar lines into scanlines.
- For each pixel $x$ in the first image:
  - Find corresponding epipolar scanline in the right image.
  - Examine all pixels on the scanline and pick the best match $x'$.
  - Compute disparity $x - x'$ and set $\text{depth}(x) = \frac{f_B}{x - x'}$. 
Correspondence search

- Slide a window along the right scanline and compare contents of that window with the reference window in the left image.
- Matching cost: SSD or normalized correlation.

Ground truth
Add constraints and solve with graph cuts

For the latest and greatest: [http://www.middlebury.edu/stereo/](http://www.middlebury.edu/stereo/)
Failures of correspondence search

- Textureless surfaces
- Occlusions, repetition
- Non-Lambertian surfaces, specularities
Dot Projections

Region-growing Random Dot Matching

1. Detect dots (“speckles”) and label them unknown
2. Randomly select a region anchor, a dot with unknown depth
   a. Windowed search via normalized cross correlation along scanline
      – Check that best match score is greater than threshold; if not, mark as “invalid” and go to 2
   b. Region growing
      1. Neighboring pixels are added to a queue
      2. For each pixel in queue, initialize by anchor’s shift; then search small local neighborhood; if matched, add neighbors to queue
      3. Stop when no pixels are left in the queue
3. Repeat until all dots have known depth or are marked “invalid”

Projected IR vs. Natural Light Stereo

• What are the advantages of IR?
  – Works in low light conditions
  – Does not rely on having textured objects
  – Not confused by repeated scene textures
  – Can tailor algorithm to produced pattern

• What are advantages of natural light?
  – Works outside, anywhere with sufficient light
  – Uses less energy
  – Resolution limited only by sensors, not projector

• Difficulties with both
  – Very dark surfaces may not reflect enough light
  – Specular reflection in mirrors or metal causes trouble

Projected Light Pattern

IR Sensor

Stereo Algorithm

Segmentation, Part Prediction

Depth Image

Body Pose
Goal: estimate pose from depth image

Real-Time Human Pose Recognition in Parts from a Single Depth Image
Jamie Shotton, Andrew Fitzgibbon, Mat Cook, Toby Sharp, Mark Finocchio, Richard Moore, Alex Kipman, and Andrew Blake
CVPR 2011
Goal: estimate pose from depth image

Challenges

- Lots of variation in bodies, orientation, poses
- Needs to be very fast (their algorithm runs at 200 FPS on the Xbox 360 GPU)
Extract body pixels by thresholding depth
Basic learning approach

• Very simple features

• Lots of data

• Flexible classifier
Features

• Difference of depth at two offsets
  – Offset is scaled by depth at center
Get lots of training data

• Capture and sample 500K mocap frames of people kicking, driving, dancing, etc.
• Get 3D models for 15 bodies with a variety of weight, height, etc.
• Synthesize mocap data for all 15 body types
Body models
Part prediction with random forests

- Randomized decision forests: collection of independently trained trees
- Each tree is a classifier that predicts the likelihood of a pixel belonging to each part
  - Node corresponds to a thresholded feature
  - The leaf node that an example falls into corresponds to a conjunction of several features
  - In training, at each node, a subset of features is chosen randomly, and the most discriminative is selected
Joint estimation

• Joints are estimated using mean-shift (a fast mode-finding algorithm)

• Observed part center is offset by pre-estimated value
