

# Discretized Schwarz Method

For discretized problem, alternating Schwarz iteration takes form

$$\begin{array}{lll} {\pmb x}_{k+\frac{1}{2}} &=& {\pmb x}_k + {\pmb R}_1^T {\pmb A}_1^{-1} {\pmb R}_1 ({\pmb b} - {\pmb A} {\pmb x}_k) \\ \\ {\pmb x}_{k+1} &=& {\pmb x}_{k+\frac{1}{2}} + {\pmb R}_2^T {\pmb A}_2^{-1} {\pmb R}_2 ({\pmb b} - {\pmb A} {\pmb x}_{k+\frac{1}{2}} \end{array}$$

- This method is analogous to block Gauss-Seidel, but with overlapping blocks
- Overall iteration matrix has form

$$(I - R_1^T A_1^{-1} R_1 A) (I - R_2^T A_2^{-1} R_2 A)$$

Parallel Numerical Alo

so this is known as multiplicative Schwarz method

1

9/66

Domain Decomposition Computation with Grids

#### **Discretized Schwarz Method**

• Eliminating  $x_{k+rac{1}{2}}$  in Jacobi version, we obtain

$$x_{k+1} = x_k + (R_1^T A_1^{-1} R_1 + R_2^T A_2^{-1} R_2)(b - Ax_k)$$

which is just Richardson iteration with *additive Schwarz* preconditioner

$$R_1^T A_1^{-1} R_1 + R_2^T A_2^{-1} R_2$$

 Symmetry of preconditioned system means it can be used in conjunction with conjugate gradient method to accelerate convergence

L

Domain Decomposition Computation with Grids Scalability and Fault Tolerance Non-Overlapping Subdomains

#### Many Overlapping Subdomains

- To achieve higher degree of parallelism with Schwarz method, we can apply two-domain algorithm recursively or use many subdomains
- If there are *p* overlapping subdomains, then define matrices *R<sub>i</sub>* and *A<sub>i</sub>* as before, *i* = 1,..., *p*
- Additive Schwarz preconditioner then takes form

$$\sum_{i=1}^p \boldsymbol{R}_i^T \boldsymbol{A}_i^{-1} \boldsymbol{R}_i$$

13/66

1

Overlapping Subdomains

el T. Heath Parallel Numerical Algorithms

#### Many Overlapping Subdomains

- Multiplicative Schwarz iteration for p domains is defined analogously
- As with classical Gauss-Seidel vs. Jacobi, multiplicative Schwarz has faster convergence rate than corresponding additive Schwarz (though it still requires coarse grid correction to remain scalable)
- But unfortunately, multiplicative Schwarz appears to provide no parallelism, as p subproblems per iteration must be solved sequentially
- As with classical Gauss-Seidel, parallelism can be introduced by coloring subdomains to identify independent subproblems that can be solved simultaneously

Michael T. Heath Parallel Numerical Algorithms

- - We have as yet achieved no parallelism, since two subproblems must be solved sequentially for each iteration, but instead of Gauss-Seidel, we can use block Jacobi approach

$$\begin{array}{lll} \pmb{x}_{k+\frac{1}{2}} &=& \pmb{x}_k + \pmb{R}_1^T \pmb{A}_1^{-1} \pmb{R}_1 (\pmb{b} - \pmb{A} \pmb{x}_k) \\ \\ \pmb{x}_{k+1} &=& \pmb{x}_{k+\frac{1}{2}} + \pmb{R}_2^T \pmb{A}_2^{-1} \pmb{R}_2 (\pmb{b} - \pmb{A} \pmb{x}_k) \end{array}$$

whose subproblems can be solved simultaneously

• With either Gauss-Seidel or Jacobi version, it can be shown that iteration converges at rate independent of mesh size, provided overlap between subdomains is sufficiently large (and independent of mesh size)

lichael T. Heath Parallel Numerical Algorithms

Overlapping Subdomains

#### Discretized Schwarz Method

• Multiplicative Schwarz iteration matrix is not symmetric, but can be made symmetric by additional step with  $A_1^{-1}$  each iteration

$$\begin{array}{rcl} \boldsymbol{x}_{k+\frac{1}{3}} &=& \boldsymbol{x}_{k} + \boldsymbol{R}_{1}^{T} \boldsymbol{A}_{1}^{-1} \boldsymbol{R}_{1} (\boldsymbol{b} - \boldsymbol{A} \boldsymbol{x}_{k}) \\ \\ \boldsymbol{x}_{k+\frac{2}{3}} &=& \boldsymbol{x}_{k+\frac{1}{3}} + \boldsymbol{R}_{2}^{T} \boldsymbol{A}_{2}^{-1} \boldsymbol{R}_{2} (\boldsymbol{b} - \boldsymbol{A} \boldsymbol{x}_{k+\frac{1}{3}}) \\ \\ \boldsymbol{x}_{k+1} &=& \boldsymbol{x}_{k+\frac{2}{3}} + \boldsymbol{R}_{1}^{T} \boldsymbol{A}_{1}^{-1} \boldsymbol{R}_{1} (\boldsymbol{b} - \boldsymbol{A} \boldsymbol{x}_{k+\frac{2}{3}}) \end{array}$$

which yields symmetric preconditioner that can be used in conjunction with conjugate gradient method to accelerate convergence

#### Aichael T. Heath Parallel Numerical Algorithms

#### main Decomposition Overlapping Subdomains Non-Overlapping Subdomains

### Many Overlapping Subdomains

- Resulting generalization of block-Jacobi iteration is highly parallel, but not algorithmically scalable because convergence rate degrades as p grows
- Convergence rate can be restored by using coarse grid correction to provide global coupling
- If  $\mathbf{R}_0$  and  $\mathbf{R}_0^T$  are restriction and interpolation matrices between coarse and fine grids, and  $\mathbf{A}_0 = \mathbf{R}_0 \mathbf{A} \mathbf{R}_0^T$ , then additive Schwarz preconditioner becomes

$$\sum_{i=0}^p \boldsymbol{R}_i^T \boldsymbol{A}_i^{-1} \boldsymbol{R}_i$$

 $\mathbb{I}$ 

#### main Decomposition nputation with Grids Non-Overlapping Subdomains Non-Overlapping Subdomain

#### Coarse Grid Correction

- Coarse grid correction is necessary to retain algorithmic scalability as number of subdomains grows
- Reasonable choice for resolution of coarse grid is √h, where h is mesh size of underlying fine grid
- Options for solving coarse grid problem include
  - Partition coarse grid problem across processors in same manner as fine grid problem
  - Solve coarse grid problem serially on one processor and broadcast results
  - Solve entire coarse grid problem redundantly in parallel on each processor
- Choice among these depends on relative size of coarse grid problem and relative speeds of communication and computation

17/66

#### Domain Decomposition Computation with Grids Scalability and Fault Tolerance Non-Overlapping Subdomains Non-Overlapping Subdomains

 Partitioning matrix and right-hand-side vector accordingly, we obtain symmetric block linear system

$A_{11}$	0	$A_{13}$	$[x_1]$		$\begin{bmatrix} \boldsymbol{b}_1 \end{bmatrix}$
0	$A_{22}$	$A_{23}$	$ x_2 $	=	$ b_2 $
$A_{13}^{T}$	$oldsymbol{A}_{23}^T$	$A_{33}$	$\lfloor x_3  floor$		$\begin{bmatrix} \boldsymbol{b}_3 \end{bmatrix}$

• Zero blocks result from assumption that nodes in  $\Omega_1$  are not directly connected to nodes in  $\Omega_2$ , but only through interface nodes in  $\Gamma$ 

1

 
 Domain Decomposition Computation with Grids Scalability and Fault Tolerance
 Overlapping Subdomains
 Overlapping Subdomains

 Schur Complement
 Non-Overlapping Subdomains
 Non-Overlapping Subdomains
 Non-Overlapping Subdomains

• We can now determine interface unknowns  $m{x}_3$  by solving system  $m{S}m{x}_3=m{\hat{b}}_3$ 

where

$$\hat{m{b}}_3 = m{b}_3 - m{A}_{13}^T m{A}_{11}^{-1} m{b}_1 - m{A}_{23}^T m{A}_{22}^{-1} m{b}_2$$

Remaining unknowns are then given by

$$egin{array}{rcl} m{x}_1 &=& m{A}_{11}^{-1}(m{b}_1 - m{A}_{13}m{x}_3 \ m{x}_2 &=& m{A}_{22}^{-1}(m{b}_2 - m{A}_{23}m{x}_3 \end{array}$$

which can be computed simultaneously

1

#### Many Non-Overlapping Subdomains

- To achieve higher degree of parallelism with Schur method, we can apply two-domain algorithm recursively or use many subdomains
- If there are *p* non-overlapping subdomains, let *I* be set of indices of interior nodes of subdomains and *B* be set of indices of interface nodes separating subdomains
- Then discrete linear system has block form

Michael T Heath

$$\begin{bmatrix} \boldsymbol{A}_{II} & \boldsymbol{A}_{IB} \\ \boldsymbol{A}_{IB}^T & \boldsymbol{A}_{BB} \end{bmatrix} \begin{bmatrix} \boldsymbol{x}_I \\ \boldsymbol{x}_B \end{bmatrix} = \begin{bmatrix} \boldsymbol{b}_I \\ \boldsymbol{b}_B \end{bmatrix}$$

where  $A_{II} = \operatorname{diag}(A_{11}, \ldots, A_{pp})$  is block diagonal

• We partition indices of unknowns in corresponding discrete linear system into three sets,  $S_1$  and  $S_2$  corresponding to interior nodes in  $\Omega_1$  and  $\Omega_2$ , respectively, and  $S_3$  corresponding to interface nodes in  $\Gamma$ 

Domain Decomposition Computation with Grids Scalability and Fault Tolerance

## Schur Complement

Block LU factorization of matrix A yields

$$egin{array}{cccc} m{I} & m{O} & m{O} \ m{O} & m{I} & m{O} \ m{A}_{13}^{-1} m{A}_{11}^{-1} & m{A}_{23}^{-1} m{A}_{22}^{-1} & m{I} \end{array} \end{bmatrix} egin{bmatrix} m{A}_{11} & m{O} & m{A}_{13} \ m{O} & m{A}_{22} & m{A}_{23} \ m{O} & m{O} & m{S} \end{array} \end{bmatrix}$$

where *Schur complement* matrix *S* is given by

$$\boldsymbol{S} = \boldsymbol{A}_{33} - \boldsymbol{A}_{13}^T \boldsymbol{A}_{11}^{-1} \boldsymbol{A}_{13} - \boldsymbol{A}_{23}^T \boldsymbol{A}_{22}^{-1} \boldsymbol{A}_{23}$$

1

# Overlapping Subdomains Non-Overlapping Subdomains Schur Complement matrix S is expensive to compute and is generally dense even if A is sparse But if Schur complement system Sx<sub>3</sub> = b̂<sub>3</sub> is solved iteratively, then S need not be formed explicity Matrix-vector multiplication by S requires solution in each subdomain, implicitly involving A<sup>-1</sup><sub>11</sub> and A<sup>-1</sup><sub>22</sub>, which can be done independently in parallel

• Conditioning of S is generally better than that of A, typically  $\mathcal{O}(h^{-1})$  instead of  $\mathcal{O}(h^{-2})$  for mesh size h, but *interface preconditioner* is still needed to accelerate convergence

ichael T. Heath Parallel Numerical Algorithms

 $\mathbb{I}$ 

Computation with Grids Scalability and Fault Tolerance

# Many Non-Overlapping Subdomains

Block LU factorization of matrix A yields system

$$oldsymbol{S}oldsymbol{x}_B = \hat{oldsymbol{b}}_B$$

where Schur complement matrix S is given by

$$\boldsymbol{S} = \boldsymbol{A}_{BB} - \boldsymbol{A}_{IB}^T \boldsymbol{A}_{II}^{-1} \boldsymbol{A}_{IB}$$

and  $\hat{\boldsymbol{b}}_B = \boldsymbol{b}_B - \boldsymbol{A}_{IB}^T \boldsymbol{A}_{II}^{-1} \boldsymbol{b}_I$ 

• As before, this system can be solved iteratively without forming *S* explicitly, and interface preconditioner is used to accelerate convergence

1

### Many Non-Overlapping Subdomains

Interior unknowns are then given by

$$\boldsymbol{x}_I = \boldsymbol{A}_{II}^{-1} (\boldsymbol{b}_I - \boldsymbol{A}_{IB} \boldsymbol{x}_B)$$

Non-Overlapping Subdomains

 All solves involving A<sup>-1</sup><sub>II</sub>, both in iterative phase for computing interface unknowns and subsequent computation of interior unknowns, can be performed on all subdomains in parallel because A<sub>II</sub> is block diagonal

 Parallel Computation with Grids Multigrid

 Parallel Computation with Grids
 Computation with Grids

- We will now consider some practical issues in implementing such grid-based computations in parallel
- For simplicity, we focus on regular finite difference grids in 2-D; unstructured meshes (e.g., finite element) and 3-D are slightly more complicated but issues are similar
- Communication is required whenever stencil for given point includes points on another processor
- For greater efficiency in message passing, all such communications for given step (iteration or time step) are bundled together by maintaining "*ghost*" points, overlapping between two subgrids

el T Heath Parallel Nu

1

Domain Decomposition Computation with Grids Scalability and Fault Tolerance Points

## **Ghost Points**

- For simple five-point stencil, single layer of ghost points suffices
- For higher-order approximation with larger stencil, more layers of ghost points may be needed for wider overlap
- Wider overlap may also benefit some algorithms, such as Gauss-Seidel with red-black ordering
- For standard nine-point stencil, corner ghost points are required, but communication between "diagonal" processors can be avoided by properly synchronizing successive horizontal and vertical communications

1

#### Parallel Numerical Algorithms

Computation with Grids Ghost Points

#### **Diagonal Trick**

- In nine-point stencil, there are two types of ghost point communication: edges must be exchanged with North/South/East/West neighbors, and corners must be exchanged with NE/SE/NW/SW neighbors
- Why not simply perform eight communication steps?
- Time to exchange ghost points can be estimated as  $T_{comm} = 4(t_s + nt_w) + 4(t_s + t_w)$
- Recall that  $t_s \gg t_w$ , so time becomes  $T_{comm} \approx 8t_s + 4nt_w$
- Can we avoid t<sub>s</sub> part of cost of moving corner points?
