HomeGrow

ECE 445 - Senior Design

Ciara Ward, Sanjana Sastry, Stephanie Sieben

April 28, 2022

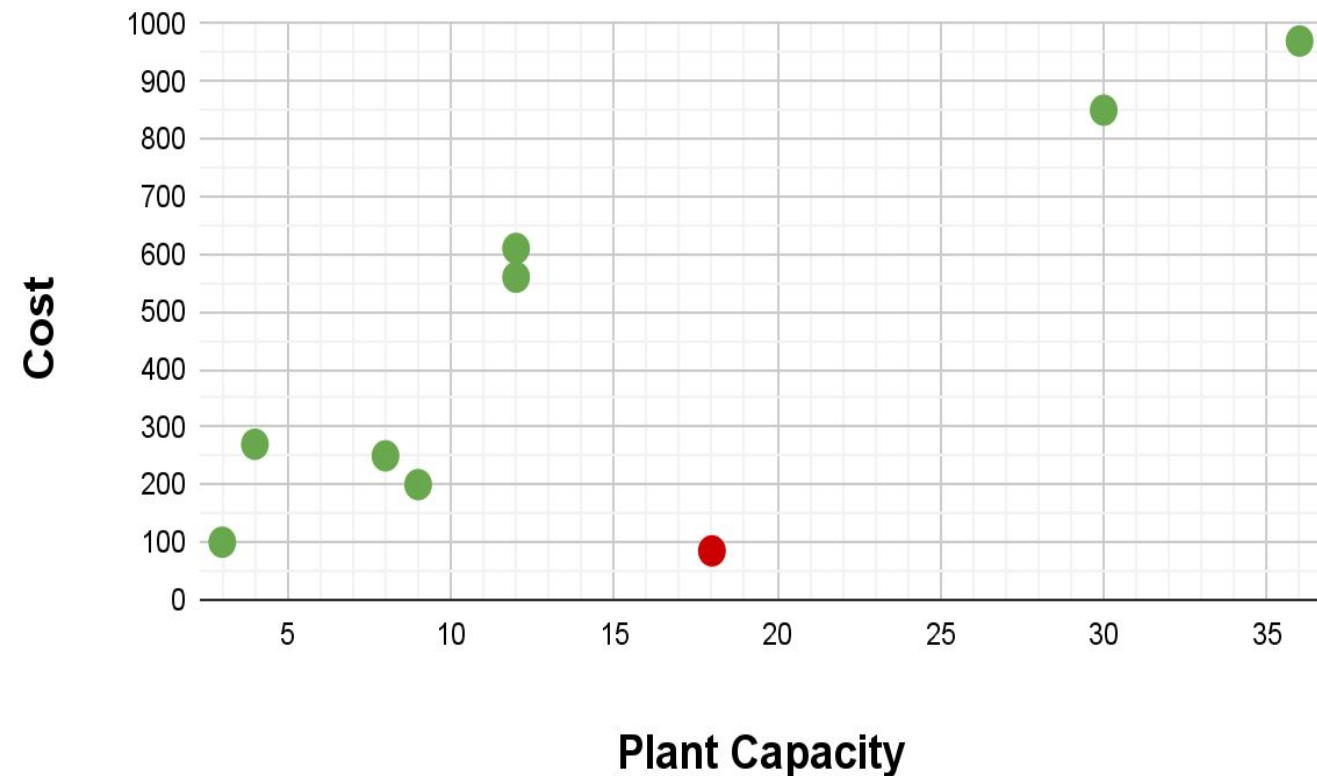

Problem Statement

Lack of Proper Access to Healthy Foods

- Healthy & organic food is difficult to find and often expensive
- At home gardening is expensive, time consuming, and requires extra space
- The current automated watering systems come at extremely high costs
- All of these factors further drives the food gap between high and low income communities

Plant Capacity v Cost

Market Average = \$33/Plant

Our Cost = \$4.72/Plant

Project Goal

Create an in-home vertical gardening system for people to grow their own produce and herbs for a more sustainable lifestyle

Design

High Level Requirements

- User interface notifies user 10 minutes before scheduled watering cycle with either:
 - Watering cycle is being skipped
 - Solenoid valve will be opened
- 15-minute watering every 24 hours
 - Exception: when moisture levels > 60% saturation
- Control system instructs LED grow lights to stay on for 12 hours and off for 12 hours.

- Originally planned a multi-tiered device
 - Sized down for efficiency and cost
- Originally planned for 1 gallon water jug as reservoir
 - Refined model with casing and put eyelet at bottom to see water level
- Display discussion
 - LCD vs. LEDs

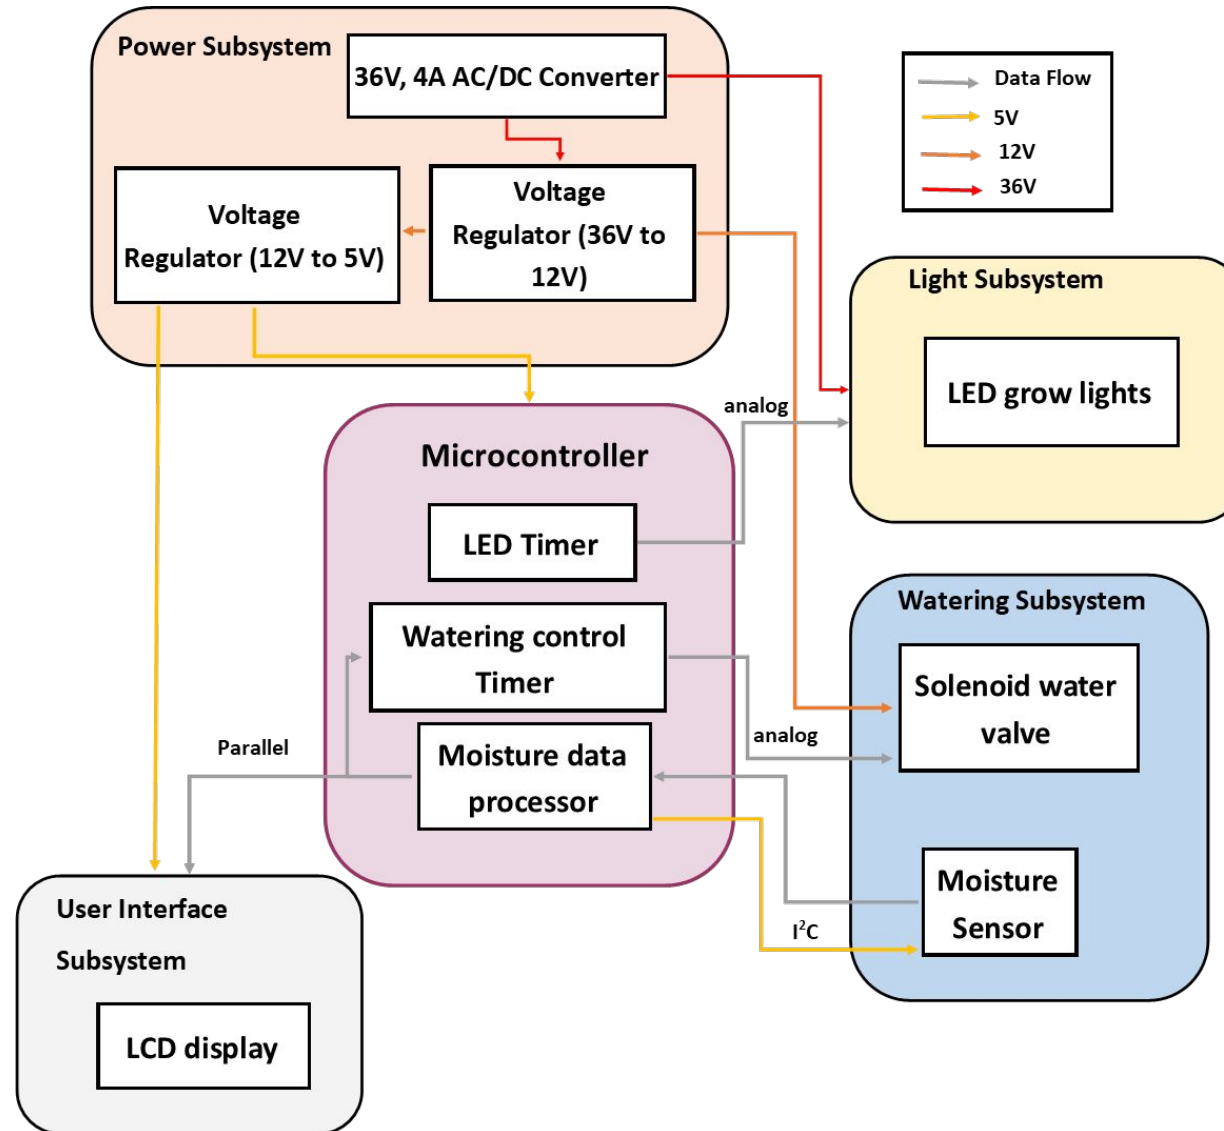

Original Design

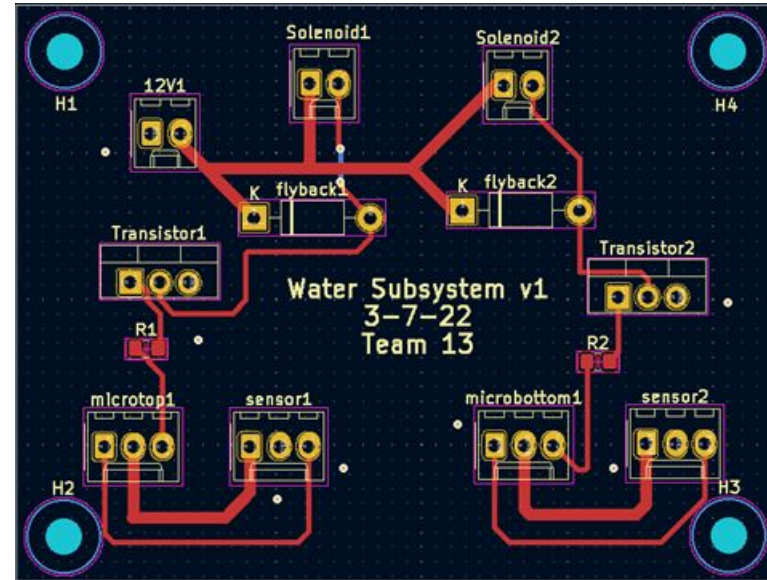

Design Mock-up

Block Diagram

PCB Layouts

Microcontroller Subsystem

- Microcontroller is able to be programmed by the computer
 - Either using Arduino IDE or Microchip Studio
 - Using the SPI programmer

User Interface Subsystem:

- Control system alerts user when water cycle is being skipped or not (10 min prior)

Lighting Subsystem:

- LED grow lights turn on when supplied with 36 volts
- Lights subsystem adheres to designated 12 hours on, 12 hours off cycle every 24 hours

Power Subsystem:

- Regulates 36 volts to 12 volts
- Regulates 12 volts to 5 volts

Watering Subsystem

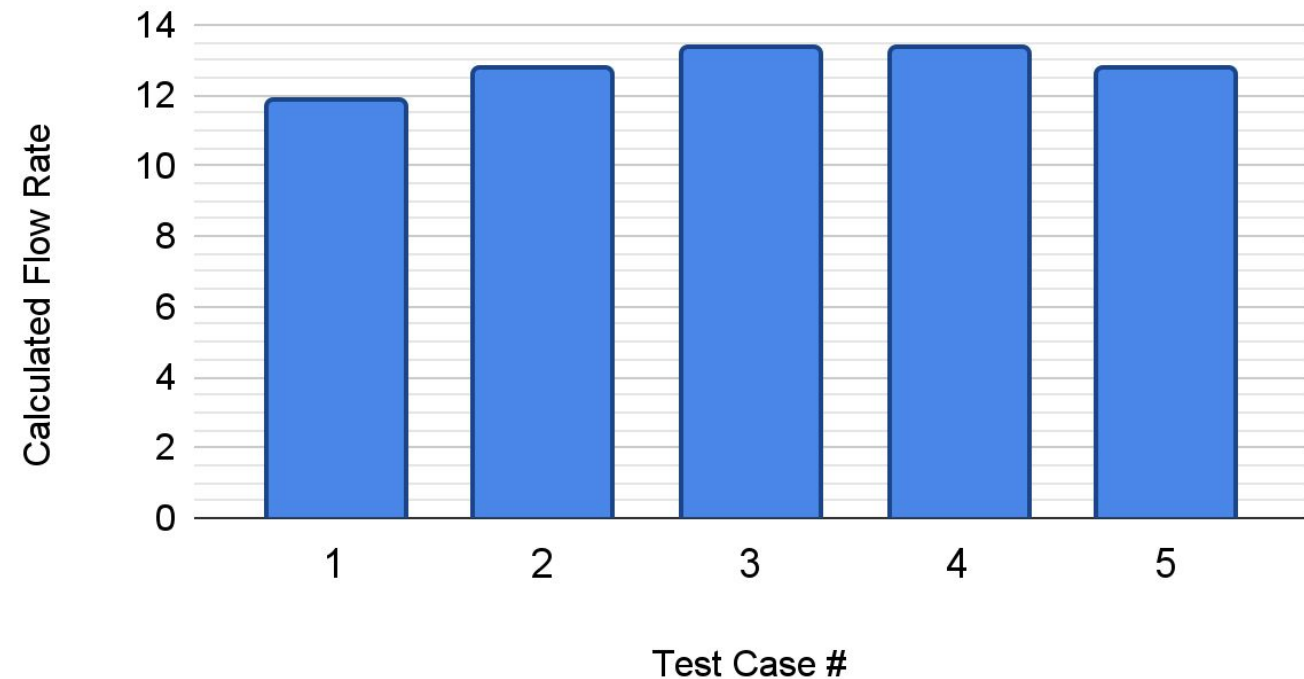

- Water valve opens when 12V applied with the power supply
- Moisture sensor gathers data on soil moisture level
- Water valve follows the desired schedule
 - If moisture level is below 60%, the valve opens
 - If moisture level is above 60%, the cycle is skipped
- Water valve remains open for 15 minutes to provide sufficient water to plants
- Solenoid valve provides at least 4oz of water in under 30 minutes

Average Flow Rate: 12.78mL/min

Test #	Duration(min)	Water Collected(oz)	Calculated Flow Rate (oz/min)	Calculated Flow Rate (mL/min)
1	10	4	.4	11.83
2	15	6.5	.43	12.72
3	15	6.75	.45	13.31
4	15	6.75	.45	13.31
5	15	6.5	.43	12.72

Calculated Flow Rate Testing

Functional Test of the subsystems

Video 1: Operation when plant needs to be watered

Functional Test of the subsystems

Video 2: Operation when plant does not need watering

Final Product

Challenges

LCD

- Arduino shut off with 5V power - potential short somewhere in the wiring
 - Changed current on potentiometer but only managed to get backlight turned on (3.3V power input)
- Further testing with a power supply overheated the LCD (5.4 V input, accidentally too high) and made it unusable
- Solution: We decided to go with a simpler and more universal solution of LED Indicators on a user interface

Microcontroller

- Programming the ATmega325PA proved to be our biggest roadblock
- Could not configure into Microchip Studio with the USBasp from the lab
- Prevented us from full system integration

Conclusion

Changes & Improvements to Design:

- Add a lid and wheels to increase portability
- MCU that has only the number of I/O pins needed
- Use real-time-clock built into a microcontroller rather than programming timers

What we learned along the way

- Integrate subsystems
- Coding ports rather than pin numbers in Microchip Studio
- PCB and hardware design in KiCad

The screenshot shows the Atmel Studio IDE interface. The title bar reads "445 proj - Microchip Studio". The menu bar includes File, Edit, View, VAssistX, Project, Build, Debug, Tools, Window, and Help. The toolbar contains various icons for file operations, editing, and debugging. The "Debug" dropdown menu is open, showing "Debug" and "Debug Browser". The "ATmega325PA" target is selected. The main window displays the "main.c" file for the "445 proj" project. The code is as follows:

```

41 //lighting subsystem Demo
42 DDRB = 0b0000
43
44 while(1){
45     void init_ports_mcu(){
46         DDRA = 0b00000001; // set port a pin 0 as an output
47         //PORTA0 is the LED pin
48         _delay_ms(20000); // 20 sec delay
49         PORTA = PORTA | (0b00000001); //Turns on bit 0
50         _delay_ms(60000); // wait 1 min
51         PORTA = PORTA & ~(0b00000001); //Turns off bit 0
52     }
53     //code for watering system
54     DDRA = 0b01010001; //pin 6 and 5 set to output and the others as input, can be all done at the start
55     Sensor_on();
56     valve_on(); // turn on the valve

```

The status bar at the bottom shows "100 %".
