Final Report for ECE 445, Senior Design, SPRING 2012

TA: JUSTINE FORTIER

2 MAY 2012
Project No. 25
Abstract

The Otter Stalker System is designed to enhance the current technology of wildlife monitoring that is available to wildlife researchers. The Otter Stalker System is designed to have optimal monitoring coverage to enhance wildlife study experiences.

When the otters are present in the study site, the sensor networks will detect their presence and location. Then, the sensors’ feedback will be send wirelessly to the main controller. The microcontroller will interpret the information received. Based on the sensors’ output, the main controller will send appropriate trigger pulse to activate the video recording of corresponding camera. The recorded video will then be saved into a memory card.

Although our design was successful, there are improvements that could be made. The audio capability of the Otter Stalker System can be improved. This will enrich the wildlife study experience as acoustic can be a useful material to learn more about otters. Besides that, a battery power indicator will also be useful because this will ease the user of the system.

The final cost of the project is higher than expected. There are several ways to reduce the cost of production and they are discussed in the Cost section.

1. Introduction
This project is in collaboration with Illinois Natural History Survey, Institute of Natural Resource Sustainability, University of Illinois Urbana Champaign in the study of the river otters. The main motivation of this project is to enhance the current technology available to wildlife researchers. The current otter habitat-monitoring method employs trailing cameras with limited range of sensing mechanism and fixed camera view. In other words, they are only able to detect and record the wildlife behaviors in one direction. To address the limitations of current habitat monitoring system, the Otter Stalker System is designed to have optimal monitoring coverage to enhance wildlife study experiences.

1.1 Purpose
The goal of this project is to improve the sensitivity of detecting the presence of otters, which is limited by the conventional habitat-monitoring methods. This system enables habitat-monitoring in all directions without compromising the effectiveness of the wildlife data obtained. Besides, it also increases the monitoring coverage of the habitat and is able to operate autonomously for up to four days.

1.2 Project Functions
The Otter Stalker System integrates two cameras with one sensing network wirelessly. When the otters are present in the study site, the sensor networks will detect their presence and location. Then, the sensors’ feedback will be send wirelessly to the main controller. The microcontroller will interpret the information received. Based on the sensors’ output, the main controller will send appropriate trigger pulse to activate the video recording of corresponding camera. The recorded video will then be saved into a memory card.

Otter Stalker System is able to detect the presence of wildlife within an area of 3m x 3m. It is weatherproof and possesses the capability of taking color day video clips and infrared night video clips with audio recording. Besides, it is inconspicuous to the otters. The signal to noise ratio (SNR) from the transmitters to the receivers is larger than 20dB. Batteries that support this system have a lifetime of at least four days as the researchers will visit the site twice a week to collect data and change the batteries.

The Figure 7.1 (all diagrams, figures, and tables appear in Chapter 7 and Appendix) shows the block diagram of the Otter Stalker System. The Sensing Module will detect the presence and position of otters at the otter study site. The information from Sensing Module is encoded into Hamming code and is sent wirelessly to the Main Controller through the Wireless Communication Module. Then, the Main Controller will analyze and interpret the information. Based on the information, the Main Controller will generate appropriate trigger pulse to the Camera Module. The trigger pulse will activate the video recording of Camera Module. Once the recording is finished, the recorded video is saved into a memory card.
1.2 Subprojects
The system consists of six subprojects, with each performs a specific task. The subprojects are described as below:

1.2.1 Sensing Module
Sensing Module plays an important role in this system as it is used to detect the presences of the otters. It consists of four Panasonic NaPiOn Spot Type PIR sensors, with two of them have a horizontal detection angle of 22° and the other two have a horizontal detection angle of 38°. All of them have a sensing length of 5m. To ensure the full coverage of the 3m x 3m area, they are placed in a designed arrangement, as shown in Figure A.1 in the Appendix.

1.2.2 Wireless Communication
The function of the Wireless Communication module is to encode the data collected from the Sensing Module and to transmit the data to the Main Controller wirelessly for further analyzing. This module can be subdivided into two sections, which are the transmitter interface and the receiver interface. The transmitter interface consists of one LINX-TXM-418-LR transmitter, one 8-bit CIP-8E encoder, one Texas Instrument MSP430G2553 microcontroller, one whip antenna, resistors and capacitors. The receiver interface is made of two LINX RXM-418-LC receivers, two 8-bit CIP-8D decoders, two whip antennas and two 0.1μF capacitors, one for each camera.

1.2.3 Main Controller
The main controller plays an important role in the Otter Stalker System as it is the brain of the system. The main controller functions to control the activation of video recording of camera module based on information provided by sensing module. Based on the feedback from the sensors, it controls the field of view of the camera by deciding which camera to be woken up. The camera’s video recording is activated by generating a trigger pulse using the main controller to the camera. Besides that, the main controller is also able to detect up to 2-bit error and correct 1-bit error as the information sent to the main controller from the decoder implements Hamming (7,4) Code.

1.2.4 Camera Module
The camera module functions to capture video when otters are present in the study site. The activation of the camera module will be controlled by main controller. The cameras will record a short-length video and store it in memory storage. Cameras are placed at specific locations as shown in the Figure A.1 to ensure the full coverage of the otter study site.

1.2.5 Power Supply
Power supply is important because it provides 3.3V voltage to all the components except the trail camera. Spy Point Pro X Plus Trail Camera originally comes with a 12V rechargeable lithium battery, thus no external power supply is needed.

1.2.6 Casing Design
The purpose of the cases is to protect the circuit from the otters and possible weather hazards.
2 Design Procedure

2.1 Sensing Module
Four sensors with smaller sensing range, instead of fewer sensors with larger sensing range (>60°), are used so that the exact position of the otter can be determined as the whole study site can be divided into four smaller areas. With this information, the Main Controller is able to decide which camera should be turned on. On the other hand, two sensors with sensing range of 38° are used at the left side and the up side of the area to make sure that the Sensing Module is actually covering the area outside of the 3m x 3m study site, as shown in the Figure A.1. The larger sensing area will be able to compensate the delay of sending the signal from sensors to cameras.

2.2 Wireless Communication Module
The Wireless Communication module is included in this system to minimize the wiring needed because the system will be operated at the outdoor and the Sensing module will be set far apart from the Camera Module. By connecting the components wirelessly, the system can also be protected from destroying by the otters. The LINX-TXM-418LR transmitter and LINX R XM-418-LR receivers are used as they are ideal for cost-effective wireless transfer of serial data in the favorable 260-470MHz band, which fulfill the requirement of the system. Besides, the transmitter and receiver are capable of sending and receiving the serial data at up to 10,000bps at a distance of up to 3,000 feet. The 8-bit CIP-8E encoder and the 8-bit CIP-8D decoders are chosen because they offer an easy to use and low-cost solution for simple remote control applications in a convenient industry standard 20-pin PDIP package. Moreover, the encoder is also power-efficient. It will enter low power sleep mode once powered-up until the transmit enable pin is pulled to ground. The Texas Instrument MSP430G2553 microcontroller is used to construct the Hamming code from the data received from the Sensing module. It is cost-effective and power-efficient. Furthermore, it consumes less area compared to standard logic gates, such as OR and AND gates in constructing the Hamming code.

2.3 Main Controller
The main controller used in this project is MSP430G2553 microcontroller from Texas Instrument. There are other good alternatives of microcontrollers such as PIC, and Arduino. However, the MSP430G2553 microcontroller is used for the following reasons:

a) It is able to accomplish the main controller functions
b) It is a low power consumption microcontroller
c) It is affordable and comes with a development kit tool that allows direct interface to a PC for easy programming, debugging, and evaluation.
d) It is easy to use as it can be programmed using C language.

The microcontroller is configured and programmed using Code Composer Studio. The hardware configuration and software program is written in C language. The Main Controller can be divided into two sub-algorithm which are Hamming Code Checking and Correction and Sensor Interpretation.
2.3.1 Hamming Code Checking And Correction Of The Main Controller
The Single Error Correction Double Error Detection (SECDED) of Hamming Code can be implemented by using the following equations\textsuperscript{[12]}:

\[
\begin{bmatrix}
1 & 0 & 1 & 0 & 1 & 0 & 1 & 1 \\
0 & 1 & 1 & 0 & 0 & 1 & 1 & 1 \\
0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 \\
\end{bmatrix}
\begin{bmatrix}
P_1 \\
P_2 \\
a \\
p_3 \\
b \\
c \\
d \\
\end{bmatrix}
\begin{align*}
\text{mod } 2 &= \begin{bmatrix}
z_0 \\
z_1 \\
z_2 \\
\end{bmatrix} \\
\end{align*}
\tag{2.1}
\]

Where
H is a parity check matrix
z is a syndrome vector

The syndrome vector, \( z \), indicates whether an error has occurred. The syndrome vector, \( z \), determines the bit position which has error. If syndrome \( z \) is a null vector, then there is no error.

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transmitted Bit</td>
<td>( P_1 )</td>
<td>( P_2 )</td>
<td>a</td>
<td>( P_3 )</td>
<td>b</td>
<td>c</td>
<td>d</td>
</tr>
</tbody>
</table>

Thus, the value of the specified bit position (determined by the syndrome vector, \( z_i \)) is inverted to perform a one-bit error correction.

2.3.2 Sensor Interpretation Of The Main Controller
After error checking and correction, the encoded data can be decoded to obtain the sensors’ output of a, b, c, and d. The sensors’ output interpretation can be implemented using if-else statement in C language. Then, the corresponding trigger pulses are generated and sent to the corresponding camera.

There is a slight modification made to the main controller after the design review. For the camera module, the camera used needs a recovery time of 10 seconds after a recording session. This is clearly a drawback to the Otter Stalker System. There might be a 10 seconds period where otters’ activity is not captured. Since two cameras are implemented, a 10 seconds difference time of activation trigger between both cameras is implemented if the otters are in the view of both cameras. Thus, the 10 seconds recovery time of the camera can be compensated. The sensors’ output interpretation of the microcontroller is shown in Figure 7.2.

2.4 Camera Module
The camera module contains two Spy Point Pro-X Plus trail cameras. Few other alternatives for camera module are considered as shown in Figure 7.3.

Thus, the Spy Point Pro-X Plus trail camera is chosen for the following reasons:

a) Record a video with audio for duration of 90 seconds
b) Video recording activation can be controlled by the main controller
c) Weatherproof and chew-proof
d) It has night vision capability with bright IR LED illumination which is inconspicuous to otters

In order to have full coverage of the otter’s study site, two trail cameras are implemented. Previously, a single rotating camera controlled by navigation module is suggested in proposal. However, the navigation module is omitted because the loud noise caused by this module might be conspicuous to the otters. However, the trail camera has a limitation of 10 seconds recovery period after each video recording session. This limitation can be compensated through the main controller.

An interface between the camera module and main controller is also needed. This is to ensure that the main controller can interact with the camera module. Since the camera is originally connected to a PIR sensor used to trigger the video recording, experiments have been carried out to look for a method to modify accordingly to this project, such that the video recording should be triggered by the Main Controller of this system. Two pins were found to be able to trigger the video recording function of the camera when they are shorted together. The voltage across these two pins is 3V. Thus, a digital N-type MOSFET (FDV301N) can be used as a switch to turn on the video recording function. The MOSFET will be the interface between the camera module and main controller.

The pin (White) with the higher voltage will be connected to the drain of the FET while the pin (Black) with the lower voltage will be connected to the source of the FET as a ground. The switch will be controlled by the output voltage of the microcontroller, which will be connected to the gate of the FET. The maximum threshold voltage of the FET is 1.06V. Theoretically, when \( V_{gs} > V_{th} \), the FET is turned on and the current is allowed to flow between the drain and the source as inversion layer is created. On the other hand, when \( V_{gs} < V_{th} \), the FET is turned off, then there is no conduction between drain and source. Therefore, when the output voltage is larger than 1.06V, the video recording will be triggered.

2.5 Power Supply

Power Supply Module is designed to provide power to the system on the otter field for at least four days. The operating voltage for each component is shown in Figure 7.4. Despite the performance of sensors, decoders and encoders are better when they are supplied with 5V voltage, regulated voltage 3.3V is provided to all units to reduce the power consumption of the system. Four Energizer Max Alkaline C Batteries, which have capacity approximately 8350mAh each, are connected in series to produce 6V voltage. Then, a 3.3V voltage regulator, LD1117V33, is used to regulate 6V to 3.3V. Since the transmitter and receiver used require power noise lesser than 20mV p-p for optimal performance, capacitors and resistors are added to reduce the noise voltage swing. There will be three sets of power units. Each set will provide power to the following modules respectively:

(a) Sensor Module and Transmitter Interface Unit
(b) Receiver Interface Unit, Main Controller Module and MOSFET switch of Camera 1
(c) Receiver Interface Unit, Main Controller Module and MOSFET switch of Camera 2
The Power Supply Module is made detachable from the rest of the components so that the substitution of different batteries size and types, depending on user’s preference, can be easily done. For extended period system operation on the otter field, alkaline batteries can be chosen for its large power storage capacity. On the other hand, rechargeable NiMH can be cost effective in the expense of the frequent labor of changing the batteries.

### 2.6 Casing Design

Three cases are made to protect the circuit. The three cases are used to shield the components as shown below:

- **(a) Sensor Case:** Four PIR sensors  
- **(b) Transmitter Case:** Transmitter Interface Unit  
- **(c) Receiver Case:** Receiver Interface Unit, Main Controller and MOSFET switch

The transmitter case and receiver case has rubber-laminated lid to effectively prevent water leakage into the cases. The trail camera is mounted on a height-adjustable stands. There are three possible stands available for us, which are monopod, tripod and microphone stand. Monopod is chosen since it is cheaper and doesn’t require further physical modifications to be applied to the project. Unlike tripod, it can be easily buried into the ground and it stands stably.
3 Design Details

3.1 Sensing Module

The horizontal detection angle of the Panasonic NaPiOn Spot Type PIR sensor is 38° and the vertical detection angle is 22° as shown in Figure A.2. Thus, for sensor b and sensor c as shown in Figure A.1, two of the sensors are rotated 90° to change their horizontal detection angle to 22°. The output of the sensor is shown in Figure A.3 and Figure A.4. As stated in the data sheet, when the sensor detects, the minimum output voltage is $V_{dd} - 0.5V$. Since $V_{dd} = 3.3V$, the minimum output voltage will be 2.8V. When the sensor does not detect, the output voltage is 0V. However, the typical output voltage obtained after performing several tests is 3.3V. The output voltage will be considered as binary logic, in which 1 = high voltage (3.3V) and 0 = low voltage (0V) when it is sent to the Wireless Communication module. The sensor with digital output is chosen over the sensor with analog output since the data from the sensors will be constructed into Hamming code, in which binary logic data will be required.

Since the sensors are separated from the camera, they will have to be mounted on some surfaces to be able to function. Besides, mounting them on the surfaces will make connecting the wires easier when putting all the four sensors in a small waterproof case. Thus, PCBs have been designed using Eagle for the sensors to mount on as shown in the Figure 7.5 and Figure 7.6. Since the sensor has a diameter of 11mm, the board will be made a bit larger than that, with its dimension is 15mm(width) x 15mm(length), to support the sensor. In order for the sensors to cover the study site completely without overlapping, the placement of the sensors has been designed as shown in Figure 7.7.

The angles shown in the Figure 7.7, which are 149.5° and 157°, are obtained by placing the PCBs of sensors side by side, with the sensing area of each sensor to be parallel with the sensing area of the sensor beside, in order to ensure that no overlapping occurs. Although there is a gap between each sensing area, it will not affect the sensing module since the gap is small (0.021m and 0.023m). Typically, the average body length of the otters is 0.978m to 1.129m, which is much larger than the gaps not covered by the sensors. Thus, as long as the otters appear in the study site, the detection of them is ensured.

According to the datasheet, the sensors have to be connected in parallel when multiple of the sensors are used. Figure 7.8 shows the schematic of the sensors. To simplify the wiring of the sensors, they are connected to a base PCB which has been designed as shown in Figure 7.9. VDD and GND are connected to the power supply while a, b, c, d are the outputs of sensors a, b, c, d respectively.

The data collected from the sensors will then be sent to the Wireless Communication Module for encoding and transmitting to the receivers attached to the Main Controller. The sensors are powered by four 1.5V batteries connected in series (total voltage provided is 6V), which is regulated to 3.3V by using a 3.3V voltage regulator.
### 3.2 Wireless Communication Module

Figure A.5 in the Appendix shows the schematic of the transmitter interface. The output of the Sensing module will be connected to the microcontroller for Hamming code implementation. By using Hamming code as a form of encoding the output of the Sensing module, 1-bit errors can be corrected and 2-bit errors can be detected. This will reduce the errors made during the data transmission significantly. Figure A.6 in the Appendix shows the programming of constructing the Hamming code. The encoder will then encode the Hamming code in a 8-bit data package as shown below:

\[
\begin{array}{cccccccc}
D7 & D6 & D5 & D4 & D3 & D2 & D1 & D0 \\
0 & d & c & b & P_3 & a & P_2 & P_1 \\
\end{array}
\]

where a, b, c, and d are either 0 (not detecting) or 1 (detecting) according to output voltage of sensor a, b, c, and d respectively and P_1, P_2, and P_3 are the parity bits where

\[
\begin{align*}
P_1 &= a \text{ XOR } b \text{ XOR } d \\
P_2 &= a \text{ XOR } c \text{ XOR } d \\
P_3 &= b \text{ XOR } c \text{ XOR } d
\end{align*}
\]

The signals encoded will then be sent to the transmitter for data transmitting at frequency 418MHz to the receiver interface which is attached to the Main Controller.

Figure A.7 shows the schematic of the receiver interface. The receiver will receive the data package sent by the transmitter and send it to the decoder for decoding. The decoded signal will then be sent to the Main Controller for further analyzing.

Since the Wireless Communication module will be attached to the same monopod as the camera, it is preferred to be as small and light as it can. Thus, all the components of the Wireless Communication module, Main Controller, and the voltage regulators of the power supply will be mounted on the PCBs, instead of protoboard which has a larger and heavier. The PCBs are designed by using Eagle PCB Design Software. Figure 7.10 and Figure 7.11 show the PCB designs for transmitter interface and receiver interface respectively.

### 3.3 Main Controller

The schematic of the main controller module is shown in Figure A.8. The main controller receives encoded Hamming Code data as inputs from the encoder of Wireless Communication module originated from Sensing module. Then, the main controller will check, correct and decode the received data. From the data, the sensors’ outputs are interpreted and the corresponding trigger pulses are generated to activate the correct camera for video recording.

The program codes written for the main controller implementation by using the main controller algorithm can be seen in the Figure A.9.
3.4 Camera Module
The schematic of the camera module is shown in Figure A.10. The N-MOSFET acts as a switch with the gate pin of NMOSFET connected to the microcontroller while both the shutter trigger pins are connected to drain and source of the NMOSFET respectively. Thus, when a trigger pulse is generated from the microcontroller to the gate of MOSFET, an inversion layer occurs which creates a channel connecting drain and source. Hence, both the shutter trigger pin will be shorted and the camera’s video recording will be activated.

3.5 Power Supply
The diagram of Power Supply Module is shown in Figure A.11. A 10Ω resistor is added in series with the power supply to attenuate the power noise. It is followed by a 10μF tantalum capacitor from VCC to ground. Shunt tantalum capacitor can reduce the noise ripple considerably. A default value, 0.1μF, bypass capacitor is added after the voltage regulator for the same reason. Beside the concern of power noise, the power consumption of the whole system is also an important issue since the system will be unmanned and work independently for a certain period. The supply current drawn from each component is shown in Figure 7.12. The total unloaded supply current drawn by the Sensing Module and Transmitter Interface Unit, which have the worst power consumption among the three set power supplies, is approximately 31.05mA according to equation (3.4).

\[
I_{cc,total} = 4I_{cc,sensor} + I_{cc,TX} + I_{cc,decoder} + I_{cc,MSP430} + I_{cc,regulator} \\
= (4 \times 5.48 + 3.4 + 0.5 + 0.23 + 5) mA = 31.05 mA
\]

Each battery provides an average voltage of 0.8V. According to the constant current performance of Energizer C-cell batteries as shown in Figure A.12, the service hours of the batteries are approximately 210 hours. The system can last for at least 8.75 days.

3.6 Casing Design
A draft of case design is shown as Figure A.13. The final product is shown in Figure A.14. The Sensor Case is cylindrical with diameter of 7cm, and height of 4cm. The Sensor Case is permanently attached on top of the Transmitter Case. Four holes are punched at the side of the Sensor Case to allow the front tips of PIR sensors to be exposed outside the cases. Then, the holes are sealed using the waterproof silicone glue.

The dimension of the Transmitter Case is 16cm x 9cm x 6.5cm. It is mounted on a metal plate which is attached to the body of monopod. The clamp can be adjusted for different heights.

The dimension of the Receiver Case is 16cm x 7cm x 6.5cm. It is mounted on a metal plate which is attached to the top of monopod. Four holes are made on the metal plate. Two of the holes allow wire connection between the camera and the MOSFET switch. The wire goes beneath the metal plate to prevent it from any possible damage. The third hole is used to mount the camera on the monopod and the last hole is placed near to the microphone position so that the performance of the microphone is
not compromised. The camera is placed behind the Receiver Case on the metal plate. Two Receiver Cases are made for two respective trail cameras.
4 Verifications

4.1 Sensing Module
Since the system will be operating outdoor to cover a 3m x 3m study site, the Sensing module must be able to output high when motion is detected in the study site and output low when no motion is detected in order for the whole system to work as desired. Two tests have been carried out to investigate the functionality of the Sensing module, which are False Alarm Test and Miss Test. The purpose of False Alarm Test is to ensure that the Sensing module will output low when no animal and human are inside the study site. The weather, such as strong wind, and the motions of trees and bushes should not have significant effects on the performance of the Sensing module. Therefore, the desired probability of the Sensing module outputting high for this test is less than 10%. On the other hand, the objective of carrying out the Miss Test is to verify that the Sensing module will output high when animals or humans are inside the study site. It should not miss detecting any motion made by animals and humans. Thus, the desired probability of the Sensing module outputting low for this test is less than 10%.

Both of the tests were carried out by using Labview Test Program. It is a user-interfaced testing program used to provide quantitative analysis of the system performance for field-testing where lab equipment is not available. User can input threshold voltage, sampling time and time duration to model multiple possible situations. The program returns the probability of miss and false alarm numerically and recent input voltage graphically. The results of both of the tests are shown in Figure 7.13. The results obtained meet the requirements, which are less than 10%.

The tolerance of the Sensing module was verified by conducting the False Alarm Test and Miss Test with the sensor array is deviated from the original position 5° each time. The two tests will be repeated until the probability is above 30%. From the test results, the maximum allowed angle deviation obtained is 20° - 25°.

4.2 Wireless Communication Module
The output of the Sensing module must be sent correctly to the Main Controller by the Wireless Communication module. Therefore, a random 8-bit signal was fed into the encoder and the exact 8-bit signal was obtained at the output of the decoder with the transmitter and receiver interfaces were placed 5m away from each other.

To estimate the performance of the receiver, the signal to noise ratio (SNR) is calculated. The sensitivity formula is given as:

\[ S_L = k \times (T_A + T_{RX}) \times BW_{3dB} \times \frac{S_o}{N_o} \]  

(4.1)

Rearranging it, the signal to noise ratio formula is:

\[ \frac{S_o}{N_o} = \frac{S_L}{k \times (T_A + T_{RX}) \times BW_{3dB}} \]  

(4.2)
Where $S_i$ is the sensitivity of the antenna

$k$ is the Boltzmann constant

$T_A$ is the temperature of the antenna

$T_{Rx}$ is the temperature of the receiver

$BW_{3dB}$ is the bandwidth of the signal

Assuming the receiver use single pole RC filter,

$$nBW = \frac{\pi}{2} BW_{3dB} \tag{4.3}$$

According to the datasheet, the noise bandwidth, $nBW$ is $280kHz^{[10]}$. Thus, the $BW_{3dB} = 178.3kHz$. The sensitivity of the receiver for $10^{-5}$ BER is typically -95dBm. Assuming the temperature of the antenna and receiver is at room temperature ($T_A = T_{Rx} = 293K$), the signal to noise ratio is

$$\frac{S_n}{N_o} = 219.248 \approx 23.4 \text{ dB} \tag{4.4}$$

In order to achieve a good performance, the measured SNR must be around the similar value. The SNR of the receiver was measured by using oscilloscope and the result is shown in Figure 7.14. The data obtained was then analyzed by using MATLAB as shown in Figure 7.15.

$$SNR = 20 \log \left[ \frac{\text{mean high voltage} - \text{mean low voltage}}{2 \times \text{mean std deviation}} \right] \tag{4.5}$$

$$= 20 \log \left[ \frac{1.3226 - 1.0695}{0.0206} \right]$$

$$= 21.7 \text{ dB}$$

The result from measurement, $\text{SNR} = 21.7\text{dB}$ is only slightly lower than the theoretical value and therefore is considered as a good result.

The tolerance of the Wireless Communication module was verified by testing the maximum distance between transmitter and receiver in which valid data is received. From the test results, the maximum operating distance obtained is 17.3m which is much better than the requirement.

4.3 Main Controller

Hamming Code Checking and Correction Test using the correct input data results is shown in Figure 7.16. From the results, it can be observed that the output data is the same as the input data. This is because
the input data into the microcontroller are without errors. Thus, the Hamming Code Checking and Correction of the Main Controller did not need to perform any correction on the input data. This is the expected result. Thus, the microcontroller is functioning correctly.

Hamming Code Checking and Correction Test using input data with one bit error results are shown in Figure 7.17. From the results, it can be observed that the Hamming Code Checking and Correction of the Main Controller perform a correction on the one-bit error input data. Thus, the output data is the same as the intended data. Thus, the microcontroller is functioning correctly and is performing its Hamming Code Checking and Correction on one-bit error data.

Sensor Interpretations Test results are shown in Figure 7.18. From the results, the LED corresponds to the generated pulse of the main controller (LED lights up if trigger pulse is high and LED does not light up if trigger pulse is low). The results obtained above are consistent with the intended results shown in Figure 7.2. Thus, the Main Controller is interpreting the sensors’ output correctly and is generating correct trigger pulse to the intended cameras of Camera Module.

4.4 Camera Module
By following the testing procedures, it can be concluded that the camera module is activated when a trigger pulse is sent by main controller. Photos are taken and saved inside the memory card. The camera is not activated when it is in the 10 seconds recovery period despite a trigger pulse is sent. This is expected due to limitation of the camera.

4.5 Power Supply
The power supply unit is able to provide constant voltage 3.3V with voltage swing 10mV p-p as shown in Figure 7.19. The power noise is much lower than the maximum required value, 20mV p-p.

By switching on the system for four days continuously, the batteries voltage drops from initial value, 5.92V to 5.66V. The system is still able to operate correctly after the four-days-power consumption test.

4.6 Casing Design
The cases are splashed with water stream. The inside of the cases are examined. The case design passes the waterproof test successfully. Then the cases are stabbed with scissors to make sure that the case design can withstand any physical attack. It passes this test successfully too.
5 Cost

5.1 Parts
The cost of parts for this system is shown in Figure C.1. Since the system consists of two trail cameras, the cost is fairly high, which is $803.33. However, it is assumed that the cost will be reduced by at least 20%, which is approximately $642.66 for the whole system, if the system is produced in larger quantity in the future. Besides, an alternative camera with cheaper cost can be used to further reduce the total cost of the system.

5.2 Labor
Referring to Figure C.2, the labor cost is estimated by using the following formula.

\[
\text{Total} = \text{Hourly Rate} \times 2.5 \times \text{Total Hours Invested} \tag{5.1}
\]

By using a rate of $30.00 and estimated time length of 240 hours each, the total is

\[
\text{Total} = 30.00 \times 2.5 \times 240 \times 3 = $54,000.00
\]
6 Conclusion

6.1 Accomplishments
All the module tests conducted yield satisfactory results and the system works perfectly as desired. The Otter Stalker System can detect motions in an area of 3m x 3m and trigger the trail camera to start the video recording. The 10s trigger delay between two camera, which is a feature desired by Illinois Natural History research group, can be implemented successfully. This feature ensures that either of cameras will record a video when otter is detected inside the field. We are able to achieve our goal to increase the quantity of video data taken if the otter is present in the field. Besides, the camera and sensors height is adjustable, thus it makes the system applicable in various geometrical landscape or circumstances.

6.2 Uncertainties
Although the power supply module can last for at least 8 days, the average service hours of the power supply module is not known. The standard power supply tolerance test is not conducted due to time constraint. By powering the system continuously for a certain period, the number of days for the system to fail due to depleted batteries will be counted. As this test can only be conducted after all modules are assembled, thus far, we are able to carry out this test for 5 days and the system is still working fine. We estimate the system can last for two weeks, but further testing is required to support our estimation.

The average lifespan of this system is not known exactly. This requires some long-term tests to obtain the necessary information. Although the system passes the waterproof and “chewproof” tests, the system might be vulnerable to other hazards such as big animals, bird nesting and others which can compromise the system efficiency. Feedback should be collected from the user to improve the system.

6.3 Future Works
This project can be further developed to make it user-friendlier. A power level indicator can be added to notify the user when the power level is low. Transceiver with internal antenna can be used to eliminate the need of external antenna and reduce the size of the case in the expense of wireless transmission ranges and efficiency. By reducing the size of the case, it can be more aesthetically presentable. Cases with camouflaged colors can be custom-made to replace the current one. Besides, the microphone feature of the camera can be further modified to improve the quality of video data obtained. This can be done by substituting the internal microphone with a directional microphone with a better performance. Furthermore, a stand, which allows the camera to tilt at desired angle, can be custom-made to replace the current monopod. This allows the camera to record at desired angle.

6.4 Ethical Issues
In the process of designing the Otter Stalker System, ethical guidelines based on the IEEE Code of Ethics had always been referred and practiced.

The main objective of this project is to enhance the current technology available to the river otter researchers in habitat-monitoring. In the accordance with code 5, which states that “to improve the understanding of technology; its appropriate application, and potential consequences”, researches had
been carried out on the current available technology, otters’ habitats and active hours in order to fulfill the requirements of this project.

Since Wireless Communication module is an essential part of this project, related Federal Communication Commission(FCC) regulations are complied. In the accordance with code 1, which states that “to accept responsibility in making decisions consistent with the safety, health, and welfare of the public, and to disclose promptly factors that might endanger the public or the environment”, the legal considerations section in the data sheets of the products used in this project has been consulted. Since the transmitter and receivers used in this project operates at 418MHz, Part 15, Section 231 of the FCC regulations, which regulate 260-470MHz band, had been adhered.

<tr>
<td>1. Sensing Module&lt;br&gt;The PIR sensor output high when motion is detected within 3m x 3m outdoor area. The conditional probability of false alarm and miss of the sensors array should be within 10%&lt;br&gt;a. Within an 3m x 3m indoor area with lesser interferences, the conditional probability of false alarm and miss of the sensors array should be within 15%&lt;br&gt;b. The sensor is able to detect motion 4.5m away&lt;br&gt;c. The output voltage vs distance from the PIR sensors should be constant with tolerance +/-0.5V</td>
<td>A 3m x 3m test site is set up at Bardeen Quad. PIR sensors are placed according to Figure 1. NI MyDAQ is used to acquire digital output data from the sensors.&lt;br&gt;-Preliminary Function Test&lt;br&gt;Before going to the field test, a basic test is conducted to make sure that the sensor is working as expected. PIR sensor output is connected to oscilloscope with trigger voltage at about 4.5V. Hand is waved across the sensor and the oscilloscope waveform is observed. The waveform should indicate the sensor output 4.5V and above&lt;br&gt;-False Alarm Test&lt;br&gt;For 15 minutes, no motion or person will be inside the test site. The sensors’ output must always be low. Within these 15 minutes, the output of the sensors will be sampled every 5 seconds. The false alarm probability is calculated and must be less than 10%.&lt;br&gt;-Miss Test&lt;br&gt;For another 5 minutes, a person will be moving randomly inside the test site. Within these 5 minutes, the output of the sensors will be sampled every 0.5 seconds. The miss probability is calculated and must be less than 10%.&lt;br&gt;&lt;em&gt;If the tests above fail, the following steps will be performed.&lt;/em&gt;&lt;br&gt;a. Within an area of 3m x 3m in a dark room, the False Alarm Test and Miss Test are repeated.&lt;br&gt;b. A person will be crossing perpendicularly through the sensor detection beam 4.5m away. The oscilloscope waveform should</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### 2. Wireless Communication Module

A bits sequence can be transferred from transmitter to receiver.

- The SNR (Signal to Noise Ratio) is more than 20 dB
- The total response time of this module should be lesser than 5ms.

**Precaution:** While dealing with this module, ESD (Electrostatic Discharge) wrist strap must be worn all the time to avoid possible malfunction of transmitter and receiver.

A random eight bits are fed into the encoder at the transmitter end. The decoder from the receiver end should output the same eight bits. The decoder outputs can be determined by eight LEDs. The transmitter and receiver should be placed 5m away. 

*If the tests above fail, the following steps will be performed.*

- The SNR of the receiver is measured with Vector Signal Analyzer.
- A 20% duty cycle pulse is generated by function generator and is inputted into the encoder. The encoder pin, which is fed with the signal pulse, is connected to oscilloscope channel 1. Then, the output from the decoder will be connected to the oscilloscope.

3. **Main Controller**

The microcontroller will output the results as stated from the truth table above by taking in 8 bits sequence inputs. It can correct one bit error.

   a. The microcontroller is able to detect two bit error.
   
   b. The microcontroller is able to correct one bit error.
   
   c. The VOH of the microcontroller should be 3.3V

The response time of this module should be lesser than 5ms.

The main controller GPIO pins will be fed in with eight bits sequences according to the truth table, Table 1. The output should be as stated as the truth table. The outputs can be tested with LEDs.

**Single Error Correction (SEC) Test**

One bit of the sequences is made intentionally wrong. The output of the microcontroller should be as stated as the truth table.

*If the tests above fail, the following steps will be performed.*

   a. The microcontroller will be fed with two different four bits sequence with distance 2. One of the GPIO pin is assigned for debugging use. When error is detected, the LED lights up. Five sample tests should be performed.

   b. The microcontroller will be fed with two different four bits sequence with distance 1. One bit of the sequences is made intentionally wrong. The output of the microcontroller is compared with its’ input. They should be the same.

   c. The output of the microcontroller is connected to a multimeter. The inputs of the microcontroller is fed with bits “1111” and the voltage of the output is measured. Input bits “1111” will always activate the camera.

   d. A 20% duty cycle pulse is generated by function generator and is inputed
4. **Camera Module**  
Camera takes photos when 3.3V is supplied.

   a. The voltage FET switch has a linear I-V curve if gate voltage is within threshold voltage and 3.3V.

   b. When 3.3V is supplied to the FET switch, the signal input voltage of the camera should be zero.

   **If the tests above fail, the following steps will be performed.**

      a. The gate voltage of the FET is connected to the batteries. The DC input voltage is regulated so that the gate voltage applied ranges from 0 to 3.5 with 0.5V spacing. The current will be measured with multimeter. If the current is too small to be measurable, a large resistor is placed in the circuit and the voltage difference between drain and source of the FET is measured.

      b. The gate voltage is applied with 3.3V using batteries with voltage regulator. The drain voltage is measured with multimeter.

5. **Power Supply**  
The power supply should be able to provide clean 5V and 3.3V.

   a. The power supply noise should be within 20mV pk-pk.

   **If the tests above fail, the following steps will be performed.**
pk.

6VDC is provided to the voltage regulators. The output of the voltage regulator must be 3.3V and 5V respectively with tolerance 5%.
