CryptoCam

(Cryptograph Camera)

Team 17: Jihoon Lee, Sameeth Gosike, and Sang Baek Han ECE 445 Design Review – Spring 2017 TA: Jose Sanchez Vicarte

1 Introduction

1.1 Objective

Taking the photograph using a camera has become such an easy task nowadays. As the technology improved, more people use smartphones to take the photograph rather than carrying an extra device that can only take the photograph. As for the smartphone, they do have the encrypted software available freely and reliably. However, the professional camera used by photojournalists and anyone related to that field still do not have access to any type of encryption. The encryption is necessary for the professional camera so that it provides the immediate protection from unexpected damage, loss, or robbery of camera [1].

Our solution to this problem is to use the additional hardware components between the camera data bus and the memory storage so that when the photo is taken, the photo will immediately get encrypted and then stored. Only the authorized user who has the access to this additional hardware with the correct corresponding key can see the decrypted image.

1.2 Background

In December of 2016, The Freedom of the Press Foundation published an open letter to the world-leading camera manufacturers such as Nikon, Sony, Canon, Olympus, and Fuji to build a camera with the encryption features for the sake of filmmakers and photojournalists. Those filmmakers and photojournalists are occasionally exposed to dangerous subjects which lead to the threat from the authoritarian governments or criminals. With their camera full of unencrypted images, they have no way to protect themselves from such risk [1].

1.3 High-Level Requirements

- Timing Requirements For benchmarking, a simple simulation using Arduino with ATmega2560 8-bit microprocessor was created [2]. The encryption process took 3 addition/subtraction operations and 1 multiplication/division operation. Using this, we tested with 1920x1080 resolution image and got an average time of 3 seconds. For the initialization process that produces the Chaotic Map, the average time was approximately 7 minutes. Since the microcontroller on the Arduino operates at 16MHz whereas the microcontroller the design will utilize operates at 200MHz. Thus the simulation results will serve as a worse-case benchmark time.
- Encryption complexity requirement Success of the encryption relies on how different the encrypted picture is from the original data. The correlation coefficient will be used as a quantitative measure of the difference, which determines the similarity between values of two adjacent pixels. Most chaotic map schemes online attained (< 0.002) of coefficient magnitude on success. We consider this as a successful encryption.

- Lossless Encryption 100% image recovery rate. The algorithm must be lossless, as are most image encryption algorithms are. It would be a huge disadvantage if algorithm poses a risk of damage in quality.
- Power constraint Typical high-quality camera batteries enable taking up to 500 pictures before running out. With 3 seconds of worst case encryption time and 7 minutes (420 seconds) of mapping time, we will need about an hour for the encryption of 500 pictures. And we want our camera to be able to run for entire day (12 hours). As an attachment to camera battery, the size of 4 of 3.7v, 3200mAh battery will be suitable to go in same space and ensure good lifetime. With capacity of 12800mAh, we want to run camera for total of 15 idle hours (taking encrypting time as 3 hours of equivalent consumption in idle mode due to shifting to operating voltage), we want average power consumption to be no more than

$$P_{average} = 3.7V \times 12800 mAh = 3.157W$$

2 Design

The design acquires the data from the camera module and utilizes the data processing unit to encrypt the data. The usage of SDRAM helps the achievement of timing requirement due to its faster speed compared to other species of memory devices.

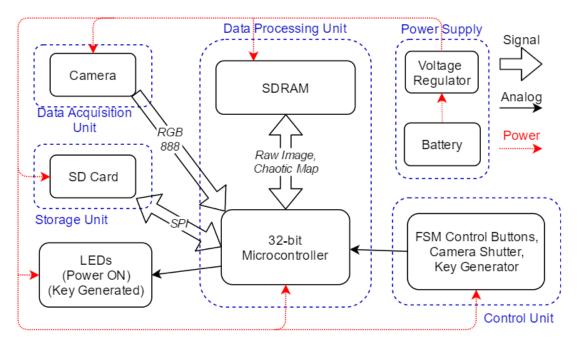

Figure 1 – Block Diagram

2.1 Data acquisition Unit

The data acquisition unit is composed of a single camera, which uses a light sensitive receptor array to acquire an optical input in RGB888 format. The RGB888 pixel data will be sent to the data processing unit for encryption and storage. The resolution will be 1920x1080 to meet the typical resolution of DSLR camera [4].

2.2 Data Processing Unit

SDRAM: AS4C64M32MD1-5BIN (Alliance Memory)

- Big memory capacity (256MB), enough to store 32 images without flushing memory
- Low dynamic power consumption (Max Supply voltage: 1.9V, Maximum current:190mA)
- Fast operating frequency (200Mhz) resulting in low memory access time (5ns). It even excels many of its SRAM counterparts.
- It is cheap (about \$10) and takes only one chip to store multiple pictures. Some SRAM counterparts can provide faster access time (0.45ns) however the price for the same memory capacity (256MB) goes beyond \$1000.

Microcontroller: TMS320F2837xD Dual-Core Delfino (Texas Instruemnt)

- Low operating voltage (1.2V) helps achieving power requirement
- High Maximum operating frequency (200Mhz) helps achieve timing requirement.
- Good amount of Flash memory (1MB) will allow more processing power and performance.
- High temperature tolerance (max 125 degrees Celcius)
- Cons: Expensive price (\$36~40).

The data processing unit is centered on a 32-bit microcontroller. A 256MB SDRAM is used to store pixel data and the variables that are needed to process the whole pixel data. One image will be 6MB as shown from the calculation below.

$$Image \ Size = \frac{1920 \ pixels \times 1080 \ pixels \times 3 \ byts \ per \ pixel}{1024 \times 1024 \ bytes \ per \ Megabytes} \approx 5.93 MB$$

The data processing unit will implement an image encryption based on chaotic logistical maps. Traditional encryption methods such as AES, IDEA, DES, and RSA are computationally complex and slow [5]. Chaotic map based encryption is better suited to professional camera use in which high speeds (close to real-time) is needed. In addition, the microcontroller that is used in this design will be able to handle such algorithms in terms of speed and computational power. The level of security of these algorithms is not a concern as they have been proven to have high success rates in numerous studies.

The chaotic map will be generated using a 80-bit chaotic key when the Key Generator button is pressed or when the camera turns off. The chaotic map will be stored in the SDRAM even in sleep-mode. Whenever the raw image is taken from the camera module, the raw image will be stored in the SDRAM. The encryption algorithm will be applied on the raw image once the camera module stops sending the raw image data.

The requirement for this unit is to dissipate less than 2.2W of power at fully functional state. (Maximum Dynamic Power) to satisfy power requirement. In addition the SDRAM access time must maximally be around 5ns in order to operate at the microcontroller's operating frequency of 200MHz.

2.2.1 Chaos Map based Image Encryption Algorithm

The algorithm used will start with an 80-bit pseudo random generated key, divided into ten session keys consisting of 8 bits each:

$$K = K_1 K_2 \dots K_{10} (ASCII)$$

Two logistic chaotic maps are employed based on the following:

$$X_{n+1} = 3.999X_n(1 - X_n)$$

$$Y_{n+1} = 3.999Y_n(1 - Y_n)$$

In order to calculate the initial condition, X_0 , three blocks of session keys are chosen i.e. $K_4K_5K_6$ and converted into a bit stream:

$$B_1 = K_{41}K_{42}..K_{48}K_{51}...K_{58}K_{61}...K_{68}$$

So then the value X_{01} is calculated as:

$$X_{01} = (K_{41} * 2^{0} + K_{42} * 2^{1} + ... + K_{48} * 2^{7}$$

$$+ K_{51} * 2^{8} + K_{52} * 2^{9} + ... + K_{58} * 2^{15}$$

$$+ K_{61} * 2^{16} + K_{62} * 2^{17} + ... + K_{68} * 2^{23}) / 2^{24}$$

Further, X_{02} can be calculated as:

$$X_{02} = \sum_{i=13}^{18} \frac{(k_i)}{96}$$

in which the k_i 's are part of the key in hexadecimal mode. Finally X_0 can be calculated as:

$$X_0 = X_{01} + X_{02}$$

A 24 digit long real number sequence is generated using the initial condition, X_0 , and the chaotic map formula $f_1, f_2...f_{24}$. However only values in the range [0.1,0.9] are retained, and the rest are discarded. The real number sequence is converted into an integer number sequence such that,

$$P_k = int(\frac{23*(f_k-0.1)}{0.8}) + 1, k = 1,2...24$$

To calculate the initial condition Y_0 , three blocks of session keys are chosen i.e. $K_1K_2K_3$ and converted to a bit stream similar to the above B_2 . Y_{01} is computed as:

$$Y_{01} = \frac{B_2}{2^{24}}$$

Further, Y_{02} is calculated as

$$Y_{02} = \frac{\sum_{k=1}^{24} B_2[P_k] * 2^{k-1}}{2^{24}}$$

Note $B_2[P_k]$ is derefercing the P_k th bit in the binary sequence B_2 . Y_0 is calculated as

$$Y_0 = Y_{01} + Y_{02}$$

The final chaos map used for the pixel manipulation is calculated by the initial condition Y_0 and the formula mentioned above, iterating for as many pixels that exist in the image. A pixel's RGB values are read in (three consecutive bytes) and the value of it's corresponding Y_n will determine the operation done on the pixel, according to the following table:

Group no.	Intervals of Y values	Operations for encryption/decryption
1	0.10-0.13, 0.34-0.37, 0.58-0.62	NOT operation, i.e. invert the bits of all three RGB bytes
2	0.13-0.16, 0.37-0.40, 0.62-0.66	$R \oplus K_4$, $G \oplus K_5$ and $B \oplus K_6$
3	0.16-0.19, 0.40-0.43, 0.66-0.70	Encryption
		$((R)_{10} + (K_4)_{10} + (K_5)_{10}) \mod 256$, $((G)_{10} + (K_5)_{10} + (K_6)_{10}) \mod 256$, $((B)_{10} + (K_6)_{10}) \mod 256$
		$(K_6)_{10} + (K_4)_{10} \mod 256$
		Decryption
		$((R)_{10}+256-(K_4)_{10}-(K_5)_{10}), ((G)_{10}+256-(K_5)_{10}-(K_6)_{10}), ((B)_{10}+256-(K_5)_{10}-(K_6)_{10}), ((B)_{10}+256-(K_6)_{10}), ((B)_{10}+256-(K_6)_{10}+256-(K_6)_{10}), ((B)_{10}+256-(K_6)_{10}), ((B)_{10}+256-(K_6)_{10}), ((B)_{10}+256-(K_6)_{10}), ((B)_{10}+256-(K_6)_{10}), ((B)_{10}+256-(K_6)_{10})$
		$(K_6)_{10} - (K_4)_{10}$
4	0.19-0.22, 0.43-0.46, 0.70-0.74	Encryption
		$NOT(R \oplus K_4)$, $NOT(G \oplus K_5)$, $NOT(B \oplus K_6)$
		Decryption
		$(NOT(R)) \oplus K_4$, $(NOT(G)) \oplus K_5$, $(NOT(B)) \oplus K_6$
5	0.22-0.25, 0.46-0.49, 0.74-0.78	Similar to Group 2 except that K_7 , K_8 and K_9 are used in lieu of K_4 , K_5 and K_6 , respectively.
6	0.25-0.28, 0.49-0.52, 0.78-0.82	Similar to Group 3 except that K_7 , K_8 and K_9 are used in lieu of K_4 , K_5 and K_6 ,
		respectively.
7	0.28-0.31, 0.52-0.55, 0.82-0.86	Similar to Group 4 except that K_7 , K_8 and K_9 are used in lieu of K_4 , K_5 and K_6 ,
		respectively.
8	0.31-0.34, 0.55-0.58, 0.86-0.90	No operations are made on R,G and B bytes

Figure 2 – Comparison Table

Possible microcontroller optimizations can include processing several pixels at a time in a parallel fashion, as well as converting the Y chaos map values into integers. Doing so will make the comparative operations when determining the pixel's operation group less computationally complex if the same was done on a floating point number.

2.3 Control unit

The control unit is responsible for controlling the FSM states between the key/map generation phase, photo-taking phase, encryption phase, and reset phase.

A shutter button will be used to signal the data processing unit to acquire data from acquisition unit. When the key generator button is pressed, a new chaotic key of 80 bits will be randomly generated. A chaotic map based off the new chaotic key will be generated and stored in a partially assigned space of the SDRAM. It will remain there until the key generator button is pressed again. While the map is processing (indicated by LED), the other buttons will be disabled until the process ends.

When the power button is pressed to turn off the camera, any raw image in the SDRAM will be force-erased to prevent the chance of hacking into SDRAM to retrieve the non-encrypted images.

A new chaotic map will be generated from a new key and the SDRAM will remain in low power mode in order to keep the map saved on the memory.

The control unit should be able to de-bounce abrupt fluctuations in signals from buttons. Otherwise, controller will be loaded with more instructions to run than needed, affecting our power requirement.

2.4 Storage Unit

The storage unit is responsible for the storage of the encrypted images after they are processed by the data processing unit. The SD card will store 3 files per picture: the encrypted image, the encrypted chaotic key, and the public key. User will need to remember the private key to decrypt the image.

The storage capacity will be on the lower side (8GB) since the main goal of the project does not include storing a large number of pictures. However, in order to read/write to the memory device from and to the microcontroller, a separate SD module will have to be included in between. This will be much more successful than trying to create a protocol in the microcontroller.

2.5 Power Supply Unit

Dynamic power consumption from microcontroller and SDRAM will be the main power drain, but datasheets have little information about internal load capacitance. Utilizing information given (operating voltage, maximum current),

These figures include power dissipated in voltage regulator.

$$P_{max}(Microprocessor, operating) = 3.7V \times 440mA = 1.628W$$
 $P_{max}(Microprocessor, idle) = 3.7V \times 210mA = 0.777W$
 $P_{max}(SDRAM, operating) = 3.7V \times 190mA = 0.703W$
 $P_{max}(SDRAM, idel) = 3.7V \times 70mA = 0.259W$
 $P_{max}(SD \ card, operating) = 3.7V \times 100mA = 0.370W$

We will use 4 3.7V, 3200mAh Li-ion battery for power supply due to its high capacity compared to other battery types. The voltage regulator will adjust voltage levels to each components. A TPA7A87 (Texas instrument) linear regulator will be used due to its high current output capacity.

2.6 Requirements and Verification

Power Supply [0 points]

Requirements	Verification
Voltage regulator must be able to deliver different supply voltage to different components • Microcontroller: 1.2V ± 0.1V at 325mA • SDRAM: 1.7V ~ 1.95V at 190mA • SDcard: 2.7~3.6V at 100mA	Probe voltage from VDD and GND pins of each components using multimeter over time. If any value outside of allowed range is detected, it is flawed.
Li-ion Battery: $3.7V \pm 10\%$ voltage supply at $0.730A$.	Probe both voltage and current over the Li- ion battery with multimeter and oscilloscope. Detect fluctuation outside of defined range.

Microcontroller[20points]

Requirements	Verification
Must be able to calculate chaotic map in less than 5 minutes with no accuracy tolerance.	Implement the same software on computer, and export the data in SD card to computer. Check data validity through comparing, and estimate the time difference through number of clock ticks * frequency.
Must be able to encrypt 1920*1080 image in 3 seconds with < 1% mismatch after all optimization processes.	Implement the same encryption on computer, and export the data in SD card to computer. Check data validity through comparing, and estimate the time difference through number of clock ticks * processor frequency

SDRAM [0 points]

Requirements	Verification	
	After an attempt to write one image to SDRAM through microcontroller, turn off the power on the module and connect SDRAM to Arduino and its clock to receive image. Compare the received image with original image to check validity.	

Algorithm [20 points]

Requirements	Verification	
Encrypted image displays less than 0.002 correlation coefficient.	Export the image to the computer, and run MATLAB functions that shows the correlation coefficiency data.	
Decrypted image matches the original image with less than 1% mismatch after optimization	Export the image to PC, and run comparison program ('diff' in Linux).	

Status LEDs & Buttons [10 points]

Requirements	Verification	
LEDs must accurately show the state transition of both Power ON/OFF and Key READY/PROCESSING	Write a separate program to communicate with Arduino to trigger state transition before using button. When single transition succeeds, trigger multiple state transition routine.	
Buttons should be debounced to register only a single input per press	Probe the microcontroller's pin connected to the buttons and display them in oscilloscope.	
Buttons must be able to trigger their corresponding FSM transition	Write a separate routine that store stream of stream transition log onto SD card for test purpose. Plug SD card to PC and verify the sequence.	

2.7 Software Flow Charts

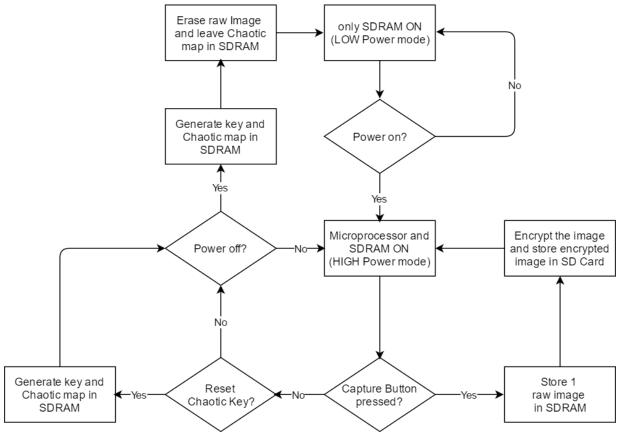

Figure 3 – System Flowchart

2.8 Circuit Schematic

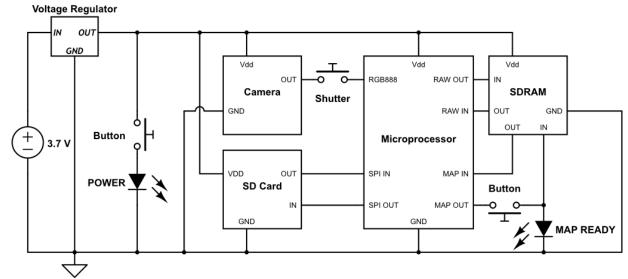

Figure 4 – Overall Circuit Schematic

2.9 Risk Analysis

The biggest risk lies in the interface between data acquisition unit and data processing unit. While input clock to the processors and camera can be synchronized, the output pixel clock of camera may not be precisely synchronized with the input clock. We will be scaling input clock inside camera so that it runs slower than the input clock, and using multiple-cycle instructions to get data.

3 Cost and Schedule

3.1 Cost Analysis

<u>LABOR</u>: We will assume to work 4hrs per day for every 5 days of week. We have 8 weeks until the final demo. We will assume that we are working 160 hours for this project. The minimum wages of \$7.25 will be used for the calculation.

Reasonable Salary = $$7.25 per hrs \times 2.5 \times 160 hrs = 2900

Since we have 3 members in our group, total labor is \$8700.

Parts: Name	<u>Price</u>
Microcontroller: TMS320F2837xD Dual-Core Delfino x 1	\$24.69
SDRAM: AS4C64M32MD1-5BIN x 1	\$13.40
SD card: Sandisk SDSDAA-2049 x 1	\$3.99
Camera: OV5642 x 1	\$39.99
Voltage Regulator: COM-00107 5V x 1	\$0.96
Battery: ICR18650 6600mAh 3.7V 1S3P x 1	\$29.50
LEDs	\$0 (ECE workshop)
Control Buttons	\$0 (ECE workshop)

TOTAL: \$8812.53

3.2 Schedule

DATE	TASKS	Workload Division
Week of 2/27	Purchase necessary parts Start Eagle PCB schematic design Start software design	Lee, Han: PCB design Gosike: Software design
Week of 3/6	Design PCB to connect all the parts. Functionality test on microcontroller, Simulate the algorithm on Arduino.	Lee, Han: PCB design, functionality test on parts Gosike: Software design & simulation on arduino
Week of 3/13	Finish assembling all the parts. Program the algorithm for microprocessor.	All: Microprocessor IDE framework setup Gosike: Software design finish up, compilation test on IDE Lee: Power consumption test, help Gosike if no trouble found Han: PCB ordering & pickup, functionality test
Week of 3/20 (Spring break)	Simulate the algorithm on microprocessor.	All: eliminate any basic errors (software compilation, malfunction) and trouble spot (possibly power)
Week of 3/27	Prepare mock-up, Integrate prototype.	Gosike, Han: eliminate any software or algorithmic error that prevents operation accuracy. Lee: Final check-up on PCB design eligibility
Week of 4/3	Refine Prototype and test integrated system.	All: Perform software optimization if requirement is not met. If not, finish any debugging needed.
Week of 4/10	Data analysis	Gosike, Lee: Output analysis with Matlab Han: Revising past data and reperform any missed simulations

4 Ethics and Safety

There are potential ethical and safety issues regarding to our project. One ethical issue is whether the photo taken does deserve to be encrypted and remained unknown for non-authorized user. As for example, secret photography is the most concern as it can be used for stalking, paparazzi, and hidden camera inside the room. If ever those photographers got caught, then it will be hard to get the evidence out of encrypted image when the access key is broken or purposely damaged.

One way to solve the above issue is to provide the alternative method to decrypt the image. But, at the same time, it raises the issue on the reliability of our encryption and decryption system. The users expect that our decryption is only allowed with one way so they can safely take the photos without being exposed to the risk of getting caught. If there is some way to recover the encrypted image and used as an evidence, then there is no point of using our camera. We will positively assume that this project will be used by modest users, who accept the responsibility as mentioned in #1 of the IEEE Code of Ethics, "to accept responsibility in making decisions consistent with the safety, health, and welfare of the public, and to disclose promptly factors that might endanger the public or the environment" [6].

At the same time, user will be using this device with a trust that we are not going to decrypt the images took by the user. First of all, we will not have access to the device of user unless we steal it from the user, which we will never do so. Secondly, we will instantly erase the password (private key) after setting it for the user so we will have no way to decrypt the images by any chance at all. Side effect will be that there will be no way to decrypt the images if the user forgets the password.

Potential safety concern we have is Li-ion battery. Since we are constantly providing power for SDRAM even in sleep-mode, the battery might get overheated if the camera is stored in a bag or heated place. We do not expect the battery to explode or fail at room temperature. If ever stored in a bag, it would be recommended for user to not keep it for a long time inside a bag. Also, we would not recommend user to carry this camera to a hot place or stay in a hot weather for a long time.
