

Reading: FPE (Franklin, Powell, Emami-Naeini, 6th edition), Sections 1.1, 1.2, 2.1-2.4, 7.2, 9.2.1.

Problems: (the first two problems are designed to test your background)

1. For each matrix and/or vector pair given below, compute their product $A \cdot B$ if possible, or explain why it is not possible.

a) $A = \begin{pmatrix} 0 & 3 \\ -1 & 2 \end{pmatrix}, B = \begin{pmatrix} 1 & 0 \\ -5 & 1 \end{pmatrix};$ b) $A = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 2 & -3 \end{pmatrix}, B = \begin{pmatrix} 1 \\ 2 \end{pmatrix};$ c) $A = (2 \ 3 \ 0), B = \begin{pmatrix} 1 & 1 \\ 2 & -2 \\ 3 & 0 \end{pmatrix}.$

Solution:

a) $A \cdot B = \begin{pmatrix} -15 & 3 \\ -11 & 2 \end{pmatrix}$

b) $A \cdot B$ is not defined because the number of columns of A is not equal to the number of rows of B .

c) $A \cdot B = (8 \ -4)$

2. Compute the magnitude and the phase of the following complex numbers:

a) $1 - 2j$ b) $2 + 3j$ c) $(1 - 2j) \cdot (2 + 3j)$

How do the answers for c) relate to those for a) and b)? State the general rule behind this.

Solution:

There are two basic forms of complex number notation: *polar* and *rectangular*. A complex number $a + bj$ (rectangular form) can be denoted as $\sqrt{a^2 + b^2} \angle \tan^{-1}(b/a)$ (polar form).

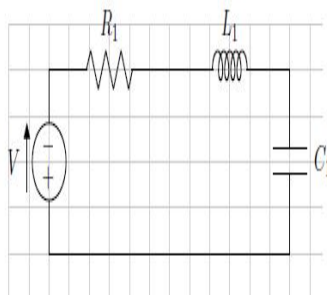

a) $1 - 2j = \sqrt{5} \angle \tan^{-1}(-2) \approx \sqrt{5} \angle -63.43^\circ$

b) $2 + 3j = \sqrt{13} \angle \tan^{-1}(3/2) \approx \sqrt{13} \angle 56.31^\circ$

c) $(1 - 2j) \cdot (2 + 3j) = \sqrt{5} \sqrt{13} \angle \tan^{-1}(-2) + \tan^{-1}(3/2) \approx \sqrt{65} \angle -7.12^\circ$

Rule: Let $z_1 = a_1 + b_1j = m_1 \angle \theta_1$ and $z_2 = a_2 + b_2j = m_2 \angle \theta_2$. Then $z_1 \cdot z_2 = m_1 \cdot m_2 \angle \theta_1 + \theta_2$.

3. Derive a state-variable model, of the form $\dot{x} = Ax + Bu$, for the following circuit:

Note that you have to decide which variables to take as the states and which one to take as the input. Make sure to declare your choice.

Solution:

Apply KVL on the loop:

$$-V_S = V_C + L \frac{dI}{dt} + IR, \quad I = C \frac{dV_C}{dt}$$

Define V_C and I as the states and V_S as the input: $x_1 = I$, $x_2 = V_C$ and $u = V_S$.

$$u = x_2 + L\dot{x}_1 + Rx_1, \quad x_1 = C\dot{x}_2$$

Write the equations in matrix form:

$$\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix} = \begin{pmatrix} -R/L & -1/L \\ 1/C & 0 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} + \begin{pmatrix} -1/L \\ 0 \end{pmatrix} u$$

Therefore, $A = \begin{pmatrix} -R/L & -1/L \\ 1/C & 0 \end{pmatrix}$ and $B = \begin{pmatrix} -1/L \\ 0 \end{pmatrix}$.

4. Convert each of the following high-order differential equations into the state-variable form:

a) $\ddot{x} + 2\dot{x} - 0.5x = 2u$ b) $x^{(4)} + \ddot{x} + x = u$

Solution:

a) Let $z_1 = x$ and $z_2 = \dot{x}$.

$$\begin{aligned} \dot{z}_1 &= z_2 \\ \dot{z}_2 &= -2z_2 + 0.5z_1 + 2u \\ \Rightarrow \begin{pmatrix} \dot{z}_1 \\ \dot{z}_2 \end{pmatrix} &= \begin{pmatrix} 0 & 1 \\ 0.5 & -2 \end{pmatrix} \begin{pmatrix} z_1 \\ z_2 \end{pmatrix} + \begin{pmatrix} 0 \\ 2 \end{pmatrix} u \end{aligned}$$

b) Let $z_1 = x$, $z_2 = \dot{x}$, $z_3 = \ddot{x}$ and $z_4 = x^{(3)}$.

$$\begin{aligned} \dot{z}_1 &= z_2 \\ \dot{z}_2 &= z_3 \\ \dot{z}_3 &= z_4 \\ \dot{z}_4 &= -z_3 - z_1 + u \\ \Rightarrow \begin{pmatrix} \dot{z}_1 \\ \dot{z}_2 \\ \dot{z}_3 \\ \dot{z}_4 \end{pmatrix} &= \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 0 & -1 & 0 \end{pmatrix} \begin{pmatrix} z_1 \\ z_2 \\ z_3 \\ z_4 \end{pmatrix} + \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \end{pmatrix} u \end{aligned}$$

5. Derive the linearization of the equation $\dot{x} = \cos x$ around the equilibrium point $x = \pi/2$ using the following two methods:

a) Use the linear Taylor approximation $f(x) \approx f(x_0) + f'(x_0) \cdot (x - x_0)$ with $x_0 = \pi/2$ to obtain the linearized equation in the form $(\dot{x} - \dot{x}_0) = f'(x_0) \cdot (x - x_0)$. Note: \dot{x} and $(\dot{x} - \dot{x}_0)$ are the same (since x_0 is constant) but we want to express the linearized equation in terms of the *deviation from the equilibrium*.

b) Make the coordinate shift $z = x - \pi/2$, linearize the system $\dot{z} = \cos(z + \pi/2)$ around $z = 0$, and then re-express the resulting equation in terms of x .

Make sure the two results agree. Provide a graphical explanation of why the linear function that you found approximates $\cos x$ well near $x = \pi/2$.

Solution:

a)

$$\dot{x}(= f(x)) \approx f(x_0) + f'(x_0)(x - x_0)$$

Moving the $f(x_0)(= \dot{x}_0)$ term to the left hand side:

$$\dot{(x - x_0)} = f'(x_0)(x - x_0)$$

Here $f(x) = \cos x$ with $x_0 = \pi/2$.

$$f'(x_0)(x - x_0) = -\sin(\pi/2)(x - \pi/2) = -(x - \pi/2)$$

$$\dot{(x - \pi/2)} = -(x - \pi/2)$$

b) $\dot{z} = \cos(z + \pi/2) = -\sin(z)$. Here $f(z) = -\sin z$ with $z_0 = 0$. Use the same routine:

$$f'(z_0)(z - z_0) = -\cos(0)(z - 0) = -z$$

$$\dot{z} = -z$$

Replacing $z = x - \pi/2$, we get the same results.
