Reading: FPE, Sections 5.3, 5.4.1, 5.4.2, 5.5, 6.1

Problems:

1. Consider the transfer function \( L(s) = \frac{s^2 + 2s + 2}{s^2 - 2s + 2} \)

   a) Plot by hand the negative \((K < 0)\) root locus for \(L(s)\), using Rules 1-6 for negative root loci. Make your root locus as explicit as possible by specifying (when applicable) the real-axis part, asymptotes, arrival and departure angles, imaginary axis crossings, and points of multiple roots. Turn in the hand plot and accompanying calculations and explanations.

   b) Plot the same root locus in MATLAB. Turn in the MATLAB plot.

Solution:

a) Rule 1: \( \# \) Poles = \( n = 2 \), \( \# \) zeros = \( m = 2 \)

Rule 2: Not applicable since there are no poles/zeros on real axis.

Rule 3: \( \# \) of asymptotes = \( n-m = 0 \)

Rule 4: Angle of departure and arrivals for the poles and zeros respectively is given by:

\[
\phi_{dep,1} = \psi_1 + \psi_2 - \phi_2 = 0 + \pi/4 - \pi/2 = -\pi/4 \\
\phi_{dep,2} = \psi_1 + \psi_2 - \phi_1 = -\pi/4 + 0 + \pi/2 = \pi/4 \\
\psi_{arr,1} = \phi_1 + \phi_2 - \psi_2 = \pi + 3\pi/4 - \pi/2 = 5\pi/4 \\
\psi_{arr,2} = \phi_1 + \phi_2 - \psi_1 = -3\pi/4 + \pi + \pi/2 = 3\pi/4
\]

Rule 5: Root locus will have multiple roots at real axis crossing, given by solving \( \frac{dK}{d\sigma} = 0 \) for \( \sigma \) where \( K(\sigma) = \frac{1}{L(\sigma)} \).

\[
K(\sigma) = \frac{\sigma^2 - 2\sigma + 2}{\sigma^2 + 2\sigma + 2} \quad \frac{dK}{d\sigma} = 0 \implies \sigma = \pm \sqrt{2}
\]

At both real axis crossings, there lies two roots. Loci will approach this point at \( \pm \pi/2 \) and leave it at 0 and \( \pi \).

Rule 6: Imaginary axis crossing is given by solving \( 1 - K L(j\omega) = 0 \) for \( K \).

\[
1 - K \frac{(j\omega)^2 + 2(j\omega) + 2}{(j\omega)^2 - 2(j\omega) + 2} = 0 \implies K = -1
\]
Consider the plant transfer function \( G(s) = \frac{1}{s^2 - 1} \). Suppose that the plant is connected in standard feedback configuration with the lead controller \( D_{\text{lead}}(s) = K \frac{s + z_{\text{lead}}}{s + p_{\text{lead}}} \) and that the control objective is to place closed-loop poles at \(-2 \pm 2j\). We assume throughout that to satisfy noise suppression requirements, the value of the lead pole is fixed at \( p_{\text{lead}} = 10 \).

a) Using the root locus phase condition, compute the value of the lead zero that achieves the pole placement objective. (If performing angle computations in MATLAB, note that MATLAB only works with radians.)

b) Using the value of \( z_{\text{lead}} \) that you computed in part a), write down the equation for the gain \( K \) that corresponds to the closed-loop poles at \(-2 \pm 2j\). Solve it for \( K \). (Hint: you have two equations, one from the real part and the other from the imaginary part, and both should give the same \( K \).)

c) Using MATLAB, plot the root locus for \( 1 + K \frac{s + z_{\text{lead}}}{s + 10} \frac{1}{s^2 - 1} = 0 \) with the value of \( z_{\text{lead}} \) found in part a). By mouse-clicking, verify that the value of \( K \) you found in part b) indeed corresponds to the desired poles.

d) Is the closed-loop system with these values of \( z_{\text{lead}} \) and \( K \) stable? Explain using the root locus.

e) Find the point of multiple roots on the locus by numerically solving the equation given by Rule 6. Verify the result by mouse-clicking on the locus.

f) Compute the closed-loop steady-state tracking error to the unit step reference using the formula \( e(\infty) = 1/(1 + D_{\text{lead}}(0)G(0)) \). Express the result in percents.

g) Write down the closed-loop transfer function \( \frac{D_{\text{lead}}(s)G(s)}{1 + D_{\text{lead}}(s)G(s)} \). Compute its DC gain. Use the DC gain to find the steady-state tracking error and verify that your result agrees with the one from part f).

h) Using MATLAB, plot the step response of the closed-loop transfer function from part g). Check that it is consistent with the result of part g).

To improve tracking, let’s add a lag controller in series with the lead controller. That is, consider the controller \( D_{\text{lead}, \text{lag}}(s) = K \frac{s + z_{\text{lead}}}{s + 10} \frac{s + z_{\text{lag}}}{s + p_{\text{lag}}} \), where \( z_{\text{lead}} \) and \( K \) are as before while \( z_{\text{lag}} \) and \( p_{\text{lag}} \) are to be chosen.

i) How large does the ratio \( z_{\text{lag}}/p_{\text{lag}} \) need to be so that the closed-loop steady-state tracking error to the unit step reference is less than 5%? Use the formula \( e(\infty) = 1/(1 + D_{\text{lead}, \text{lag}}(0)G(0)) \).

j) Fix some values of \( z_{\text{lag}} \) and \( p_{\text{lag}} \) which satisfy the condition from part i). Write down the closed-loop transfer function \( \frac{D_{\text{lead}, \text{lag}}(s)G(s)}{1 + D_{\text{lead}, \text{lag}}(s)G(s)} \). Compute its DC gain and verify that it guarantees tracking within 5%.

k) Using MATLAB, plot the step response of the closed-loop transfer function from part j). Check that the tracking error is improved as predicted in parts i) and j).

l) Using MATLAB, plot the root locus for \( 1 + K \frac{s + z_{\text{lead}}}{s + 10} \frac{s + z_{\text{lag}}}{s + p_{\text{lag}}} \frac{1}{s^2 - 1} = 0 \) with the lead zero, lag zero, and lag pole as above. Do we still get poles at approximately \(-2 \pm 2j\) for the same gain value \( K \)? If not, go back and make adjustments to the values of \( z_{\text{lag}} \) and \( p_{\text{lag}} \), making sure that the ratio \( z_{\text{lag}}/p_{\text{lag}} \) still satisfies the condition of part i). (Hint: the lag zero and lag pole need to be very close to the origin, so as not to interfere with the lead zero and lead pole.) Is the system stable for this value of \( K \)? Explain by carefully studying the root locus.

Turn in your hand work as well as MATLAB plots. Accuracy of numerical answers up to the second decimal point is acceptable.
Solution:

a)

\[ L(s) = -\frac{1}{K} \Rightarrow \angle L(s) = \pi + 2\pi \ell \]

\[ \angle L(s)|_{s=-2+2j} = \angle \frac{s + z_{\text{lead}}}{s + 10} \left. \frac{1}{s^2 - 1} \right|_{s=-2+2j} = \pi + 2\pi \ell \]

\[ \phi_1 + \phi_2 + \phi_3 - \psi_1 = \pi - \tan^{-1} \left( \frac{2}{3} \right) + \pi - \tan^{-1} 2 + \tan^{-1} \left( \frac{2}{8} \right) - \psi_1 = \pi + 2\pi \ell \]

\[ 146.3099^\circ + 116.5651^\circ + 14.0362^\circ - \psi_1 = 180^\circ + \ell 360^\circ \]

\[ \Rightarrow \psi_1 = 96.9112^\circ \Rightarrow \tan(180^\circ - \psi_1) = \frac{2}{2 - z_{\text{lead}}} = 8.25 \]

\[ \Rightarrow 0.25 = 2 - z_{\text{lead}} \Rightarrow z_{\text{lead}} = 1.7576 \]

b)

\[ 1 + K \frac{s + 1.7576}{s + 10} \left. \frac{1}{s^2 - 1} \right|_{s=-2+2j} = 0 \]

\[ (s + 10)(s^2 - 1) + K(s + 1.7576)|_{s=-2+2j} = 0 \]

\[ s^3 + 10s^2 + (K - 1)s + (1.75K - 10)|_{s=-2+2j} = 0 \]

\[ 8 - 0.2424K - (66 - 2K)j = 0 \Rightarrow K = 33 \]

c) An alternative way is to use command `rlocfind`

d) Yes, because with those values of \( z_{\text{lead}} \) and \( K \), all closed loop poles should be on LHP. LHP poles would be \( p_{1,2} = -2 \pm 2j, p_3 = -6 \)

e)

\[ b(s) \frac{da(s)}{ds} - a(s) \frac{db(s)}{ds} = 0 \]

\[ \Rightarrow (s + 1.7576)(3s^2 + 20s - 1) - (s^3 + 10s^2 - s - 10) = 0 \]

\[ \Rightarrow 2s^3 + 15.2728s^2 + 35.152s + 8.2424 = 0 \]

\[ s = -0.2636 \text{ (valid)}, s = -3.6864 \pm 1.4293j \text{ (not valid)} \]
f) 
\[ e(\infty) = \frac{1}{1 + D(0)G(0)} = \frac{1}{1 + 33 \left( \frac{1.75}{10} \right) \left( \frac{1}{1} \right)} = -0.2094 \approx 21\% \]

g) 
\[ G_{cl}(s) = \frac{G(s)D_{lead}(s)}{1 + G(s)D_{lead}(s)} = \frac{33 \frac{s + 1.7576}{(s + 10)(s^2 - 1)}}{1 + 33 \frac{s + 1.7576}{(s + 10)(s^2 - 1)}} = \frac{33(s + 1.7576)}{s^3 + 10s^2 + 32s + 48} = \frac{33s + 58}{s^3 + 10s^2 + 32s + 48} \]
\[ G_{cl}(s) = \frac{33 \times 1.7576}{48} = 1.2094 \]
\[ e(\infty) = 1 - G_{cl}(0) = -0.2094 \]

h) 

![Graph of step response](Image)

i) 
\[ D_{lead,lag}(s) = K \frac{s + z_{lead}}{s + p_{lead}} \]
\[ D_{lead,lag}(0)G_{c}(0) = -K \frac{z_{lag}}{P_{lead}P_{lag}} = -33 \frac{1.7576}{10} \frac{z_{lag}}{P_{lag}} \]
\[ |e_{\infty}| \leq 0.05 \Rightarrow \left| \frac{1}{1 - 5.8 \frac{z_{lag}}{P_{lag}}} \right| \leq 0.05 \]
\[ \Rightarrow 5.8 \frac{z_{lag}}{P_{lag}} \geq 21 \Rightarrow \frac{z_{lag}}{P_{lag}} \geq 3.62 \]

j) Choose \( z_{lag} = 0.04, P_{lag} = 0.01 \)
\[ D(s) = 33 \frac{s + 1.7576s + 0.04}{s + 10} \frac{s + 0.01}{s + 0.01} \]
\[ G_{cl}(s) = \frac{G(s)D(s)}{1 + G(s)D(s)} = \frac{33s^2 + 59.321s + 2.32}{s^4 + 10.01s^3 + 32.1s^2 + 49.311s + 2.22} \]
\[ G_{cl}(0) = \frac{2.32}{2.22} = 1.045 \Rightarrow |e(\infty)| = 0.045 \]

k)
We choose our lag’s zero-pole very close to the origin, so we expect to see that with \( K = 33 \), the closed loop poles to be very close to \(-2 \pm 2j\). As you can see from the plots, the closed-loop poles would be \( p_{1,2} = -1.9644 \pm 2.0171j \), \( p_3 = -6.034 \), \( p_4 = -0.0464 \) which are all on LHP. Therefore, the closed-loop system is stable.

3. Consider the transfer function \( G(s) = \frac{1}{s^2 + 0.5s + 1} \).

   a) Use the formulas given in class (taken from the book by Kuo, Section 9.2) to compute the resonant frequency \( \omega_r \), resonant peak \( M_r \), and bandwidth \( \omega_{BW} \) for \( G(j\omega) \).

   b) Use a computer to plot the magnitude \(|G(j\omega)|\) as a function of \( \omega \) (you can use the \texttt{bode} or \texttt{bodemag} command in MATLAB). Mark the resonant frequency \( \omega_r \), resonant peak \( M_r \), and bandwidth \( \omega_{BW} \) on the graph. Check agreement with the values you computed in a).

   \textit{Solution:}

   a) 
   \[
   G(s) = \frac{1}{s^2 + 0.5s + 1} = \frac{1}{s^2 + 2\zeta\omega_n s + \omega_n^2} \Rightarrow \omega_n = 1, \zeta = 0.25
   \]
   \[
   \omega_r = \omega_n \sqrt{1 - 2\zeta^2} = 1 \times \sqrt{1 - \frac{1}{8}} = 0.9354
   \]
   \[
   M_r = \sqrt{\frac{1}{\left(1 - \left(\frac{\omega}{\omega_n}\right)^2\right)^2 + 4\zeta^2 \left(\frac{\omega^2}{\omega_n^2}\right)}}|_{\omega = \omega_r} = \sqrt{\frac{1}{(2\zeta^2)^2 + 4\zeta^2(1 - 2\zeta^2)}} = \sqrt{\frac{64}{15}} = 2.065 = 6.3dB
   \]
\[\omega_{BW} = \omega_n \sqrt{1 - 2\zeta^2 + \sqrt{2 + 4\zeta^4 - 4\zeta^2}} = \sqrt{1 - \frac{1}{8} + \sqrt{2 + \frac{1}{64} - \frac{1}{4}}} = 1.4845\]

b)

4. For each of the transfer functions given below, draw the Bode plots (both magnitude and phase) by hand, using the techniques discussed in class. Explain all steps in your drawing procedures. Note that the transfer functions are not given in Bode form.

a) \[KG(s) = \frac{s + 10}{s(s + 5)}\]  
b) \[KG(s) = \frac{8s}{s^2 + 0.2s + 4}\]  
c) \[KG(s) = \frac{s^2 + 0.1s + 1}{s(s + 0.2)(s + 4)}\]

After you’re done, check your results using MATLAB. (Note that the \texttt{bode} command in MATLAB plots magnitude in decibels.) Turn in both the hand sketches and the MATLAB plots.

Solution:

a) 

Bode form: \[KG(s) = 2\frac{s + 1}{s(\frac{5}{2} + 1)}\]

Break points: \(\omega = 0, \omega = 5, \omega = 10\)

| \(|KG(j1)| = 2|\)

Slope: \(-1 \rightarrow -2 \rightarrow -1\)

Phase: \(-90^\circ \rightarrow -180^\circ \rightarrow -90^\circ\)

b) 

Bode form: \[KG(s) = 2\frac{s}{(\frac{s}{2})^2 + 0.05s + 1}\]

Break points: \(\omega = 0, \omega = 2\)

| \(|KG(j0.01)| = 0.02|\)

Slope: \(+1 \rightarrow -1\)

Phase: \(+90^\circ \rightarrow -90^\circ\)
c) 

Bode form: 

\[ KG(s) = \frac{1}{0.8 \left( \frac{s}{0.2} + 1 \right) \left( \frac{s}{4} + 1 \right)} \frac{s^2 + 0.1s + 1}{s^2} \]

Break points: \( \omega = 0.2, \omega = 1, \omega = 4 \)

\[ |KG(j0.01)| = 125 \]

Slope: -1 \( \rightarrow \) -2 \( \rightarrow \) 0 \( \rightarrow \) -1

Phase: -90° \( \rightarrow \) -180° \( \rightarrow \) 0° \( \rightarrow \) -90°
