Plan of the Lecture

- ▶ Review: prototype 2nd-order system
- ▶ Today's topic: transient response specifications

Goal: develop formulas and intuition for various features of the transient response: rise time, overshoot, settling time.

Reading: FPE, Sections 3.3–3.4; lab manual

Prototype 2nd-Order System

$$H(s) = \frac{\omega_n^2}{s^2 + 2\zeta\omega_n s + \omega_n^2}$$

By the quadratic formula, the poles are:

$$s = -\zeta \omega_n \pm \omega_n \sqrt{\zeta^2 - 1}$$
$$= -\omega_n \left(\zeta \pm \sqrt{\zeta^2 - 1}\right)$$

The nature of the poles changes depending on ζ :

- $\zeta > 1$ both poles are real and negative
- $\zeta = 1$ one negative pole
- $\zeta < 1$ two complex poles with negative real parts

s =
$$-\sigma \pm j\omega_d$$

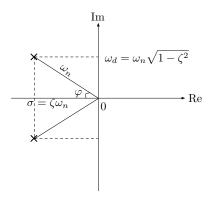

where $\sigma = \zeta \omega_n, \ \omega_d = \omega_n \sqrt{1 - \zeta^2}$

Prototype 2nd-Order System

$$H(s) = \frac{\omega_n^2}{s^2 + 2\zeta\omega_n s + \omega_n^2}, \qquad \zeta < 1$$

The poles are

$$s = -\zeta \omega_n \pm j \omega_n \sqrt{1 - \zeta^2} = -\sigma \pm j \omega_d$$

Note that

$$\sigma^{2} + \omega_{d}^{2} = \zeta^{2}\omega_{n}^{2} + \omega_{n}^{2} - \zeta^{2}\omega_{n}^{2}$$
$$= \omega_{n}^{2}$$
$$\cos\varphi = \frac{\zeta\omega_{n}}{\omega_{n}} = \zeta$$

2nd-Order Response

Let's compute the system's impulse and step response:

$$H(s) = \frac{\omega_n^2}{s^2 + 2\zeta\omega_n s + \omega_n^2} = \frac{\omega_n^2}{(s+\sigma)^2 + \omega_d^2}$$

► Impulse response:

$$h(t) = \mathscr{L}^{-1} \{ H(s) \} = \mathscr{L}^{-1} \left\{ \frac{(\omega_n^2/\omega_d)\omega_d}{(s+\sigma)^2 + \omega_d^2} \right\}$$
$$= \frac{\omega_n^2}{\omega_d} e^{-\sigma t} \sin(\omega_d t) \qquad \text{(table, # 20)}$$

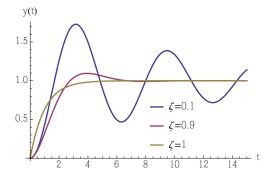

► Step response:

$$\mathscr{L}^{-1}\left\{\frac{H(s)}{s}\right\} = \mathscr{L}^{-1}\left\{\frac{\sigma^2 + \omega_d^2}{s[(s+\sigma)^2 + \omega_d^2]}\right\}$$
$$= 1 - e^{-\sigma t}\left(\cos(\omega_d t) + \frac{\sigma}{\omega_d}\sin(\omega_d t)\right) \qquad \text{(table, #21)}$$

2nd-Order Step Response

$$H(s) = \frac{\omega_n^2}{s^2 + 2\zeta\omega_n s + \omega_n^2} = \frac{\omega_n^2}{(s+\sigma)^2 + \omega_d^2}$$
$$u(t) = 1(t) \qquad \longrightarrow \qquad y(t) = 1 - e^{-\sigma t} \left(\cos(\omega_d t) + \frac{\sigma}{\omega_d}\sin(\omega_d t)\right)$$

where
$$\sigma = \zeta \omega_n$$
 and $\omega_d = \omega_n \sqrt{1 - \zeta^2}$ (damped frequency)

The parameter ζ is called the *damping ratio*

- $\zeta > 1$: system is overdamped
- $\zeta < 1$: system is underdamped
- $\zeta = 0$: no damping $(\omega_d = \omega_n)$

2nd-Order Step Response

$$H(s) = \frac{\omega_n^2}{s^2 + 2\zeta\omega_n s + \omega_n^2} = \frac{\omega_n^2}{(s+\sigma)^2 + \omega_d^2}$$
$$u(t) = 1(t) \qquad \longrightarrow \qquad y(t) = 1 - e^{-\sigma t} \left(\cos(\omega_d t) + \frac{\sigma}{\omega_d}\sin(\omega_d t)\right)$$

where $\sigma = \zeta \omega_n$ and $\omega_d = \omega_n \sqrt{1 - \zeta^2}$ (damped frequency)

We will see that the parameters ζ and ω_n determine certain important features of the transient part of the above step response.

We will also learn how to pick ζ and ω_n in order to *shape* these features according to given *specifications*.

Transient Response Specifications: Rise Time

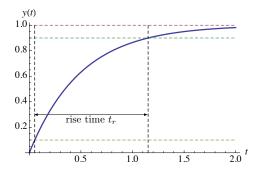

Let's first take a look at 1st-order step response

$$H(s) = \frac{a}{s+a}, \qquad a > 0 \qquad \text{(stable pole)}$$

DC gain = 1 (by FVT)

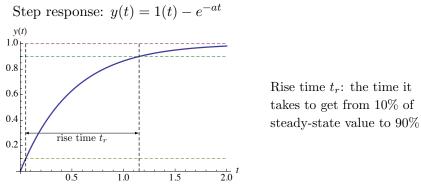

Step response:
$$Y(s) = \frac{H(s)}{s} = \frac{a}{s(s+a)} = \frac{1}{s} - \frac{1}{s+a}$$

 $y(t) = \mathcal{L}^{-1}\{Y(s)\} = 1(t) - e^{-at}$

Rise time t_r : the time it takes to get from 10% of steady-state value to 90%

Rise Time

In this example, it is easy to compute t_r analytically:

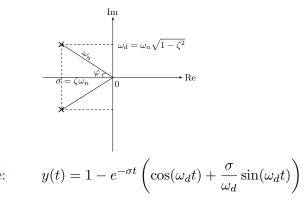

$$1 - e^{-at_{0.1}} = 0.1 \qquad e^{-at_{0.1}} = 0.9 \qquad t_{0.1} = -\frac{\ln 0.9}{a}$$
$$1 - e^{-at_{0.9}} = 0.9 \qquad e^{-at_{0.9}} = 0.1 \qquad t_{0.9} = -\frac{\ln 0.1}{a}$$
$$t_r = t_{0.9} - t_{0.1} = \frac{\ln 0.9 - \ln 0.1}{a} = \frac{\ln 9}{a} \approx \frac{2.2}{a}$$

Transient Response Specs

Now let's consider the more interesting case: 2nd-order response

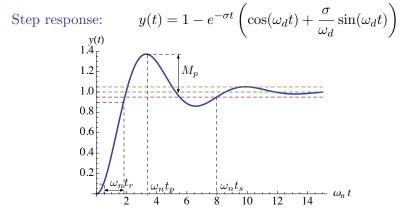

$$H(s) = \frac{\omega_n^2}{s^2 + 2\zeta\omega_n s + \omega_n^2} = \frac{\omega_n^2}{(s+\sigma)^2 + \omega_d^2}$$

where $\sigma = \zeta \omega_n \, \omega_d = \omega_n \sqrt{1 - \zeta^2} \qquad (\zeta < 1)$

Step response:

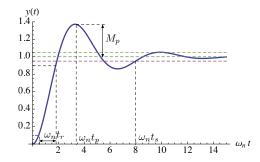

Transient-Response Specs

▶ rise time t_r — time to get from $0.1y(\infty)$ to $0.9y(\infty)$

- overshoot M_p and peak time t_p
- ▶ settling time t_s first time for transients to decay to within a specified small percentage of $y(\infty)$ and stay in that range (we will usually worry about 5% settling time)

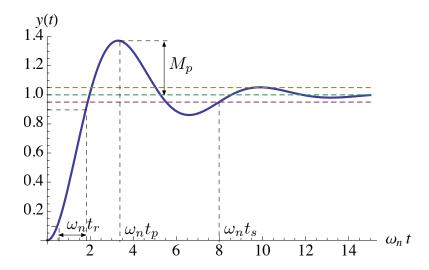

Transient-Response (or Time-Domain) Specs

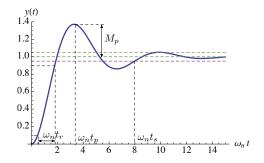

Do we want these quantities to be large or small?

- $\blacktriangleright t_r$ small
- M_p small
- $\blacktriangleright t_p$ small
- $\blacktriangleright t_s$ small

Trade-offs among specs: decrease $t_r \longrightarrow$ increase M_p , etc.

Formulas for TD Specs: Rise Time

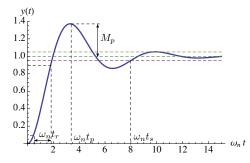

Rise time t_r — hard to calculate analytically. Empirically, on the normalized time scale $(t \rightarrow \omega_n t)$, rise times are *approximately* the same

 $w_n t_r \approx 1.8$ (exact for $\zeta = 0.5$)

So, we will work with $t_r \approx \frac{1.8}{\omega_n}$

(good approx. when $\zeta \approx 0.5$)

Formulas for TD Specs: Overshoot & Peak Time

 t_p is the first time t > 0 when y'(t) = 0

$$y(t) = 1 - e^{-\sigma t} \left(\cos(\omega_d t) + \frac{\sigma}{\omega_d} \sin(\omega_d t) \right)$$
$$y'(t) = \left(\frac{\sigma^2}{\omega_d} + \omega_d \right) e^{-\sigma t} \sin(\omega_d t) = 0 \text{ when } \omega_d t = 0, \pi, 2\pi, \dots$$

so $t_p = \frac{\pi}{\omega_d}$

Formulas for TD Specs: Overshoot & Peak Time

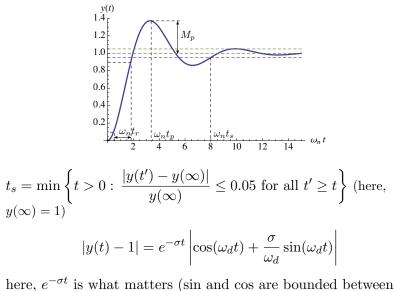

We have just computed $t_p = \frac{\pi}{\omega_d}$

To find M_p , plug this value into y(t):

$$M_p = y(t_p) - 1 = -e^{-\frac{\sigma\pi}{\omega_d}} \left(\cos\left(\omega_d \frac{\pi}{\omega_d}\right) + \frac{\sigma}{\omega_d} \sin\left(\omega_d \frac{\pi}{\omega_d}\right) \right)$$
$$= \exp\left(-\frac{\sigma\pi}{\omega_d}\right) = \exp\left(-\frac{\pi\zeta}{\sqrt{1-\zeta^2}}\right) \qquad -\text{exact formula}$$

Formulas for TD Specs: Settling Time

 ± 1), so $e^{-\sigma t_s} \le 0.05$ this gives $t_s = -\frac{\ln 0.05}{\sigma} \approx \frac{3}{\sigma}$

Formulas for TD Specs

$$H(s) = \frac{\omega_n^2}{s^2 + 2\zeta\omega_n s + \omega_n^2} = \frac{\sigma^2 + \omega_d^2}{(s+\sigma)^2 + \omega_d^2}$$

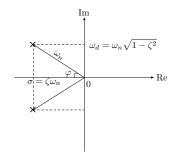

$$t_r \approx \frac{1.8}{\omega_n}$$
$$t_p = \frac{\pi}{\omega_d}$$
$$M_p = \exp\left(-\frac{\pi\zeta}{\sqrt{1-\zeta^2}}\right)$$
$$t_s \approx \frac{3}{\sigma}$$

TD Specs in Frequency Domain

We want to *visualize* time-domain specs in terms of *admissible pole locations* for the 2nd-order system

$$H(s) = \frac{\omega_n^2}{s^2 + 2\zeta\omega_n s + \omega_n^2} = \frac{\sigma^2 + \omega_d^2}{(s+\sigma)^2 + \omega_d^2}$$

where $\sigma = \zeta\omega_n$
 $\omega_d = \omega_n \sqrt{1-\zeta^2}$
Step response: $y(t) = 1 - e^{-\sigma t} \left(\cos(\omega_d t) + \frac{\sigma}{\omega_d} \sin(\omega_d t) \right)$

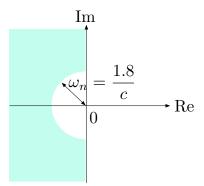

$$\omega_n^2 = \sigma^2 + \omega_d^2$$
$$\zeta = \cos \varphi$$

Rise Time in Frequency Domain

Suppose we want $t_r \leq c$ (*c* is some desired given value)

$$t_r \approx \frac{1.8}{\omega_n} \le c \qquad \Longrightarrow \qquad \omega_n \ge \frac{1.8}{c}$$

Geometrically, we want poles to lie in the shaded region:

(recall that ω_n is the magnitude of the poles)

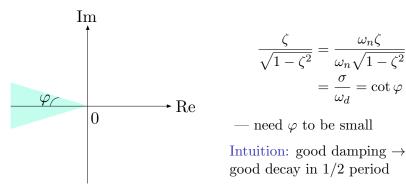

Overshoot in Frequency Domain

Suppose we want $M_p \leq c$

$$M_p = \underbrace{\exp\left(-\frac{\pi\zeta}{\sqrt{1-\zeta^2}}\right)}_{\text{decreasing function}} \le c$$

— need large damping ratio

Geometrically, we want poles to lie in the shaded region:

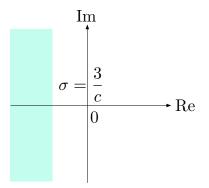

Settling Time in Frequency Domain

Suppose we want $t_s \leq c$

$$t_s \approx \frac{3}{\sigma} \le c \qquad \Longrightarrow \qquad \sigma \ge \frac{3}{c}$$

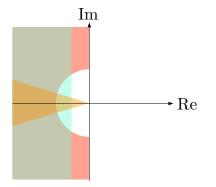

Want poles to be sufficiently fast (large enough magnitude of real part):

Intuition: poles far to the left \rightarrow transients decay faster \rightarrow smaller t_s

Combination of Specs

If we have specs for any combination of t_r, M_p, t_s , we can easily relate them to allowed pole locations:

The shape and size of the region for admissible pole locations will change depending on which specs are more severely constrained.

This is very appealing to engineers: easy to visualize things, no such crisp visualization in time domain.

But: not very rigorous, and also only valid for our prototype 2nd-order system, which has only 2 poles and no zeros ...
